UTILISING OLD WOOLLEN DRESSES.—Mrs. P. Rice read the following paper:—"A good way of making use of old woollen costumes, cardigans, jumpers, &c., is to cut them up for children's clothes. The chief point in making these up is to avoid much handling of the material once the article has been cut out, as ravelling of the wool happens very easily. To avoid this, outline with a machine right around the pattern before cutting it out, but this is not absolutely necessary provided the making up of the article is proceeded with as soon as possible after cutting out. Place the pattern on the material (which has previously been washed, then unpicked, and pressed), but do not stretch or pull it whilst cutting out, as it is easily pulled out of shape. If the original article has stripes or pattern, these can be so applied that they appear suitably on the little garment. Wherever possible, use the ribbed cuffs and bottoms of jumpers for the sleeves and the bottom of small jumper or dress, but if these parts are too worn to be used again, a very effective binding for edges is military braid, which can be had in all colors to tone, and is quite easy to apply. Any buttons may be covered with pieces of the material, and the whole cost of the small garment need not exceed that of a few press studs and braid. Bloomers and knickers have elastic in knees and waist, and to complete the outfit, a cap of the material is easily made of the odd pieces. The lower part of worn singlets can be used in the same manner for small singlets, merely by stitching up the side seams and crocheting an edging round the neck opening and arm holes."

CHILDREN'S FEEDERS.—Mrs. J. Ferguson gave the following directions for making children's feeders:—"Purchase some shelving oilcloth, cut out the feeders, and bind with bias binding. The feeders can be washed after each meal. For a table mat to place in front of the child, a piece of bound white table oilcloth saves spots on the tablecloth. If these hints are put into practice a good deal of washing will be saved."

DRESSMAKING HINTS FOR HOME WORKERS.—Mrs. G. Beckman read the following paper:—"When cutting out long, close-fitting sleeves from plain materials, it is often difficult to get it narrow enough to be really smart without being uncomfortable, tight, and apt to burst at the seams. To overcome this, cut the sleeves on the bias instead of the straight of the material. Cut in this way, it is the material and not the seam that

'gives' to any muscular exertion. The material will resume its shape when the strain is released, whereas the seam will not do this. *Method of Facing Skirts, &c.*—There are often occasions when it is necessary to face the lower edge of a skirt. For instance, if a skirt is made of tweed, a great deal of bulkiness is avoided if the lower edge is faced with a piece of lining or silk, cut on the cross. Cut the lining or silk on the cross, making it about 3½ in. wide, join it, then press the seams well. Turn in the edges of facing piece, and press. Place the skirt on the table, and tack on the facing; then slipstitch and press well. Facings should be cut, according to the shape of the edge to be finished. For straight edges, cut the facing on the straight of material, and if a shaped piece needs to be faced, either cut the facing the same shape or on the cross. For flared skirts, the facing should always be on the cross. When making flared dresses or skirts, it is advisable to hang on a dresshanger for a few days, when there will be no trouble in hemming up the skirt evenly. *A Pillowcase-making Hint.*—When making pillowcases, it is a good plan to purchase circular pillow cotton, i.e., there is no seam in the side of the case when made. Cut the material the length required, allowing about 1½ in. each end for a hem. Then cut eight lengths of tape, 7 in. long and 1½ in. wide. Fold in the material three lengthways, and make a crease, or mark with a tracing-wheel, where tapes are to be placed. Next, crease the ends of the case ready for the hem. Have the tapes ready, and insert them when stitching the hems. The idea for the hem on each end is that the pillowcases may be turned, so that four portions of the case get the wear instead of two. There is a saving of time in making, also in washing, as there are no corners to collect dust or feathers from the pillows. (Secretary, Mrs. Burford.)

#### PARUNA.

July 11th.—Present: 14 members.

**CONTROL OF SAND.**—In the course of an address on this subject, Mr. E. Edwards advised following the sand hills as early as possible in July, then sow them down with about 20 lbs. of oats and a dressing of 35 lbs. to 40 lbs. of super per acre. When the oats were well established, graze lightly for the first time, then as the plants became stronger they could be grazed a little heavier; after a while the sheep could be left on them. The ground would be well packed and contain all the roots and hold the sand from drifting. If the whole of the paddock was of a sandy nature, Mr. Edwards said it would pay to treat the whole area the same. By this method one not only held the sand in its place, but also provided good feed for many more sheep.

**VEGETABLE GARDEN ON THE FARM.**—Paper read by Mr. J. Altmann. Every farm should have a garden in which to grow vegetables for home use. Choose a piece of ground which is sheltered from the west and south winds or make a break around to prevent the wind from damaging and breaking the young plants. A good dressing of well-rotted stable manure should be applied, dug in and left rough for a week or two; then a light sprinkling of slack lime raked in, and the plot would be ready for planting. Choose the right kinds and plant them at the right time. In planting cabbage and cauliflower choose the strongest plants and set them out at least 2 ft. apart each way. A few of the leading kinds that do well in this district are Burpee (they grow quickly and have large heads); Henderson's Succession does as well, and heads all the year round. Cauliflowers.—Green Leaf and Yates' Main Crop are the two best for this district. Cabbage and cauliflowers should not be forced too much from the start. Water frequently for the first few days, then two waterings a week for a couple of

DAY-OLD CHICKENS—17s. 6d. per dozen, £6 per 100. Free on rail, Salisbury.

Further particulars can be obtained from the Manager, Parafield Poultry Station, Salisbury.

C. F. ANDERSON, Manager.

weeks. Later, a good flooding every week. Hoe between the plants a day after each watering when the plants begin to form heads, then they can be forced to grow quickly by using blood manure, sulphate of ammonia, and liquid manure. Tomatoes are one of the best crops for summer. The plot should be prepared in July by digging a trench 2ft. 6in. to 3ft. wide and 18in. deep. Give the soil a good layer of pig manure, cover it up and see that it is well trodden down. Apply a layer of well-rotted stable manure, cover it up, and leave it till planting time. Space the plants 2ft. 6in. apart. Leading kinds for this district are Matchless, American Coreless, Earliana, and Early Jewel. All are heavy croppers and do well if watered sufficiently until they flower, then leave off to allow the fruit to set. When fruit has set, water heavily and give liquid manure to obtain good-quality fruit. Peas should also be planted in July. The best kinds are William Hurst, Te Aroha, and Little Jim. Te Aroha is a very heavy cropper, with large pods. Peas should not be put in when fresh stable manure has been dug in; they do better without. Root vegetables, such as carrots, parsnips, turnips, and beet should be planted from March to May.

A meeting was also held on June 20th when an address dealing with the subjects, "Mixed Farming" and "Wheat Varieties" was delivered by Mr. W. J. Spafford (Deputy Director of Agriculture). Twenty-nine members and three visitors attended. (Secretary, Mr. F. Sumner.)

#### PARRAKIE (Average annual rainfall, 14.51in.).

The meeting held on July 11th was attended by 22 members and 16 visitors, when Mr. Kirkwood, manager of the Lameroo branch of the Bank of Adelaide, delivered an address, "Farm Finance." With the aid of a blackboard, the speaker illustrated a method of bookkeeping on the farm. (Secretary, Mr. W. Watts.)

#### REMARK (Average annual rainfall, 10.93in.).

Meeting held July 31st. The Chairman (Mr. O. Weste) presided over a good attendance of members and visitors. The annual report was presented and officers elected. Mr. E. Seary gave an address, "A Review of the Dried Fruit Industry." Mr. H. Howie also spoke. (Secretary, Mr. W. Meier.)

### SOUTH AND HILLS DISTRICT.

#### BLACKWOOD (Average annual rainfall, 27in. to 29in.).

After the annual report had been presented and officers elected, Dr. J. Davidson, D.Sc., Entomologist at the Waite Research Institute, delivered an address. "The Life History of *Aphelinus Malt.*" Twelve members and 13 visitors, including members from the Clarendon and Cherry Gardens Branches, attended. (Secretary, Mr. R. Quinn.)

#### CURRENCY CREEK.

The Annual Meeting was held on July 14th, and was attended by 13 members and visitors. The annual report was presented by the Secretary, Mr. D. Gordon, and officers elected for the ensuing year.

#### INMAN VALLEY (Average annual rainfall, 26in. to 27in.).

Mr. A. Fuller (Chairman) presided over an attendance of 15 members and a large number of visitors, including members from the Port Elliot Branch, at the Annual Meeting held on July 10th. The annual report and balance-sheet were presented. Mr. H. C. Pritchard (General Secretary Agricultural Bureau) addressed the meeting. (Secretary, Mr. H. Lewis.)

#### IRONBANK (Average annual rainfall, 33in. to 34in.).

July 23rd.

Members and visitors from Blackwood and Cudlee Creek met at Mr. Geo. Pole's orchard to inspect some apple trees which had borne a fine crop of fruit. Different methods of pruning and their effects upon the trees were discussed, and one member from each district represented pruned a tree which will be kept under observation. Afternoon tea was provided by the Ladies Guild. (Secretary, Mr. C. Morgan.)

#### KANGARILLA.

Nine members and several visitors attended the annual meeting, which was held on August 5th. The Secretary, Mr. T. Golder, presented the annual report, and officers were elected for the ensuing 12 months.

# THE IMPLEMENT CO.

Offer a Complete Line of

## Harvesting Machinery

Don't risk a whole year's work when you can ensure against loss by getting light running, easily handled harvesting machinery on which you can always depend to harvest and market your crop. You will find in the Implement Co. line the finest materials and workmanship—and, what's best of all, years of satisfactory service.

**HORWOOD-BAGSHAW  
"GASTON" HEADER.**

The simplest, easiest running, and most effective Reaper Thresher in Australia. Sizes, 8ft. and 10ft. cut. This machine has fully earned its name—"The Better Built Header."

**HORWOOD-BAGSHAW  
"ILLMAN" STRIPPER.**

The Horwood-Bagshaw "Illman" Stripper is the result of many years close attention to the requirements of Mallee Farmers, and we are confident in offering this machine to fill the demands of the most exacting user. Made in 8-ft., 9-ft., and 10-ft. sizes.

~~~~~  
Write for catalogs and prices of the above, also "Horwood-Bagshaw" Winnowers, "Austral" Binders, "Horwood-Bagshaw" Wheat Elevators, "Frost & Wood" Hay Rakes and Hay Balers.

# THE IMPLEMENT COMPANY

BANK AND BLYTH STREETS, ADELAIDE.

#### LANGHORNE'S CREEK (Average annual rainfall, 14.84in.).

March 12th.—Present: 33 members and six visitors.

Mr. E. Laurie, of the Irrigation and Drainage Commission, gave a lecture, "On Its Conservation and Use."

Meeting held May 5th. Present: 24 members and visitors. Mr. Geo. Quinn (Horticultural Instructor) addressed the meeting on the subject, "Citrus Culture."

Eighteen members attended the meeting held on June 11th, when Mr. A. H. R.D.A., read a paper, "The Currant."

The Annual Meeting was held on July 9th, there being present 20 members and four visitors. After the election of officers the meeting took the form of a discussion. Messrs. J. Natt and M. Cleggett spoke in favor of dual-purpose cattle whilst the breeds were supported by Messrs. J. Bray and N. Wetherill.

A successful social and dance was held on July 22nd. Delegates from neighboring branches attended. (Secretary, Mr. H. Follett.)

#### LENSWOOD AND FOREST RANGE (Average annual rainfall, 35in. to 36in.).

July 28th.—Present: 12 members.

MARKETING PRODUCE.—The meeting took the form of a debate on the subject, "Should Growers Market Their Own Produce?" Mr. J. Vickers, opening the debate for the affirmative, said that since time immemorial the market place had been the centre of exchange of primary produce. Market day had been looked upon as the day of the week when everybody was in town, and that mode of marketing was still in vogue to this day because it contained advantages which could not be had by any other method. Marketing one's own produce the personal touch was acquired between the grower and the buyer, and buyers as a rule preferred that, as they were surer of what they were buying. Co-operative methods and concerns had from time to time been started, but he considered that costs in general, especially labor, were too high in Australia for that form of marketing. When the marketing was left more to the grower he could do it more cheaply than when left to others who had little or no interest in making things. He thought their produce was not adaptable for auction marketing, as there were many different grades, sizes, &c., which could not be judged by the appearance of the top. Supply and demand ruled every market, and the present practice was the method of allowing the former to operate. Mr. W. J. Bishop took the opposing side. He said the present system was entirely out of date. He spoke against auction marketing because of the danger of collusion, and that would mean that goods would go for the lowest bid. He suggested a scheme of selling through commission agents and keeping it co-operative. By that means a trained salesman would be selling instead of gardeners who often knew little of the ethics of salesmanship. It would mean that pressure would be necessary to get the growers to act unanimously, when they could sell through an organized channel, demand a price instead of the buyer as at present quoting. Other members also spoke, and considered that the proposed scheme was worth consideration. (Secretary, Mr. B. Lawrence, Lenswood.)

#### LONGWOOD (Average annual rainfall, 37in. to 38in.).

The meeting of August 9th was held at the residence of Mr. R. Lewis. Mr. W. H. presided over an attendance of seven members. The party was afforded the opportunity of inspecting the orchard, and a review was made of the fruit trees prior to pruning. (Secretary, Mr. J. R. Coles.)

#### McLAREN FLAT.

The annual social, held on July 24th, was well attended. Prizes won at the Produce Competitions were distributed. A presentation was made by the members to the retiring Secretary, Mr. C. Robertson. A musical programme and dancing concluded the evening. (Secretary, Mr. A. Bruce.)

#### MILANG (Average annual rainfall, 15.13in.).

Meeting held July 9th. Present: 14 members. A paper, "The Farm Garden," presented by Mr. W. Yelland, and a keen discussion followed. (Secretary, J. P. Bagley.)

#### MOUNT BARKER (Average annual rainfall, 31.66in.).

The Annual Meeting was held on August 6th, when officers were elected for the ensuing year.

On September 10th Mr. A. Hilton, B.Sc., of the Murray Bridge High School, gave the address, "Agricultural Education in America."

**TO ENSURE  
RECOGNITION**

Present: 30 members and visitors. Mr. H. Peters gave a demonstration of milk testing. Mr. C. Vereo gave a resume of the proceedings of the Laren Flat Annual Social. Interesting data on pig fattening tests conducted by Mr. Peters were submitted by Mr. A. Peters. (Secretary, Mr. J. Black.)

## LANDS TO BE C

Lands in the Hundreds of BAR  
BOO, BURGOYNE, CALDWELL, CHILL  
COOTRA, CUMMINS, GILES, GOODE, HAGO  
KIANA, KOONGAWA, McLACHLAN, MITCHELL, NICK  
YAH, PASCOE, PEACHNA, PINKAWILLINIE, PYGERY, RIPON  
RUSSELL, SOLOMON, TOOLIGIE, WALLALA, WANNAMANA, WOO  
KATA, WUDINNA, YALANDA, and YANINEE.

When offered, full particulars will be published in the *Government Gazette*, and plans and detail may be obtained from the Secretary for Lands, Box 293A, Adelaide.

---

## LIST OF LANDS OPEN.

The attention of intending applicants for land is directed to the Official List of Lands Open, which is published half-yearly (in January and July). The list shows the areas, localities, prices, short general descriptions, &c., of the sections available, and the conditions under which they may be applied for.

Copies of the list may be obtained on application to the Secretary for Lands, Adelaide.

---

## APPLICATIONS FOR LAND.

Intending applicants for any lands which are open for application are reminded that application may be made for the whole or any portion of a block. The Land Board has power to allot portions of a block if considered advisable, and to adjust the purchase-money or rent. If only portion of a block is applied for, deposit of a proportionate amount must be made, and the successful applicant would be required to pay cost of survey of the subdivision.

---

## ADVANCES TO SETTLERS.

The administration of the various Acts dealing with advances to settlers has been committed to the State Bank of South Australia by the State Bank Act, 1925. All applications should be made to the Chairman, Board of Management, State Bank, Pirie Street, Adelaide.

R. S. RICHARDS, Commissioner of Crown Lands.

a barn free of either pest. I take it that much depends on whether you make it a regular practice of storing large quantities of wheat every year or whether you have simply in view a temporary emergency. It should not be impossible to render the barn mouse-proof, but the trouble is that mice find admittance in most unexpected ways, and are therefore difficult to control in any type of barn. As for weevil, the only practical remedy that I know of is to place the grain in an air-tight vessel. In the course of time the grain develops a sufficiency of carbonic acid gas to destroy any weevil that may be present. It seems to me, therefore, that for the purpose the most effective form of storage that you could adopt would be to shoot the wheat into ordinary galvanized iron tanks of the type used for storing water, care being taken to seal down the overhead trap door hermetically. I realise, of course, that it involves a rather heavy initial expenditure, but it is the type of expenditure that would last for a life time, and would be absolutely effective against both weevil and mice. Beyond that, it is difficult for me to give you any other advice, except to make your barn as mouse-proof as you are able, and to be careful not to store wheat that is at all damp.

---

[Replies supplied by Mr. W. J. SPAFFORD, Deputy Director of Agriculture.]

### Ensilage.

If ensilage is made in a hole on limestone ground, will the material be injuriously affected to the extent of it killing horses? (Rosedale Agricultural Bureau.) Reply—Whenever ensilage is made in a hole in the ground there is some waste through the outside and top developing mould, and the amount of waste because of this, is greater in limestone country than where the soil is more clayey in nature. This is due to the fact that limestone soils allow more air to get at the ensilage than is the case with soils of heavier texture. If horses eat the moulded part of the ensilage there is some danger of digestive troubles developing, but provided only clean, well-made ensilage is fed to the animals, horses do well on it, and the quality is just as good from a limestone pit as from the very best of silos. Because of the friable nature of limestone soils, pits must be made of the same shape as ordinary earth dams, and a good deal of batter must be given to the sides. When making ensilage in such pits, the material is spread out and each fresh load is driven right into the pit on top of what has already been spread. This driving backwards over the material consolidates it very well and helps make a much better ensilage than if no such pressure was used.

### Fodders for Pigs.

What sort of green fodder is best for pigs, and can mangels be used for this purpose? (Rosedale Agricultural Bureau.) Reply—Pigs utilise all kinds of green feed to advantage when fed to them in conjunction with grain, and of the green fodders that can be grown in your conditions, lucerne is easily the best for these animals. Mangels are a very useful pig food, provided—(a) that they have been stored for some time before being fed to pigs, and (b) that they are fed in conjunction with grain of some kind. After mangels have been lifted from the ground they are topped and rooted, and stacked in clumps of the same shape as the heaps of broken road metal so common on our roadsides. The stacks have vent-pipes built into them, and are covered first with straw and then with earth. When stored, mangels mature and are changed from a fairly ~~by~~ <sup>to</sup> feed, when fresh from the soil, into a first class watery forage. If mangels ~~are~~ <sup>are</sup> not to be stored, they should be lifted and be allowed to wilt for a few days before ~~it~~ <sup>it</sup>, ~~State~~ <sup>State</sup> ~~D.~~ <sup>D.</sup> ~~to~~ <sup>to</sup> farm livestock, and then they should be sliced and fed in conjunction ~~with~~ <sup>as</sup> foodstuff.

## AGRICULTURAL VIEWS AND COMMENTS

### Imperial Bureau Conference.

At Lower North Conference will be held at Lyndoch on Thursday, February 31. The Lyndoch Branch (J. S. Hammat, of Williamstown, Secretary), make the local arrangements, and members of Branches in the Conference district requested to forward papers to be read at the Conference to the General Secretary, Imperial Bureau, Adelaide, at least a fortnight prior to February 26th. The Conference will commence at 10.30 a.m.

### Empire Marketing Board.—How Farmers are kept in touch with Research.—The Empire Marketing Board's Report.

How the Empire Marketing Board keeps farmers in touch with the latest results of scientific research is surveyed in the Empire Marketing Board's Report, containing the answers to questions from all Empire Governments. An Introduction has been written by the Director, F.R.S. ("The Dissemination of Research Results among Agricultural Producers." H.M. Stationery Office, 1s. net.).

Report outlines the methods adopted for "getting across" scientific results to farmers on the land in over 40 different Dominions, Colonies, Provinces, States, etc., and, states the preface, be of considerable interest in all Empire countries as a source of suggestions and a summary of experience.

Mr Daniel Hall points out that the most effective method of diffusing information among farmers is by personal visits of instructors, experts, &c., to individual farms. The best appears to be visits of the farmer to demonstration farms and experimental stations. The less intimate the personal contacts, the less effective the education will be. Lectures, broadcasting, films, bulletins, and journals all suffer from this disability. British experience, which is paralleled by the Bureau system of South Australia, shows that meetings for discussion provide a greater stimulus than the pure lecture, even if discussions follow the latter.

broadcasts, films, bulletins, "better farming" trains, and other methods are used. A development of the demonstration train idea which is described is a motor van which is attached a van containing the exhibits. The instructor tours about visiting farms and giving lectures and demonstrations with his van in the district. This method has not yet been tried in the Empire.

### Books Received.

The Board acknowledges the receipt of the following publications:—

"English Plough," by J. B. Passmore, M.Sc. Published by The Oxford Press, London. Price, 7s. 6d.

"Dissemination of Research Results Among Agricultural Producers." Empire Marketing Board, No. 33. Price, 1s.

"Report of 1929 of the Colorado (U.S.A.) Agricultural Experimental Station.

"Report for Empire Butter," E.M.B. Report No. 34. Price, 1s. net.

"Infectious Necrotic Hepatitis) of Sheep in Australia," by A. W. Woodhouse and I.R. Bulletin No. 46.

## AGRICULTURAL INQUIRIES.

A. J. PERKINS, Director of Agriculture.]

"Losses of wheat?" (A.J.M., Woodhouse)  
"Influence on the one hand..."

**Feeding Value of Oats.**

The difference, if any, of the food value in these oats—Lachlan, Algerian, Early Burt, Mortgage Lifter? (Scott's Bottom Agricultural Bureau.) Reply—As far as we know, Algerian and Mortgage Lifter are one and the same variety of oats, and even if not so they are so very similar in every way that they can be grouped together. The analyses and feeding value of the three oat varieties are as follows:—

*Crude Nutrients.*

|                         | Early Burt. | Lachlan. | Algerian. |
|-------------------------|-------------|----------|-----------|
|                         | %           | %        | %         |
| Water .. . . .          | 13.3        | 13.3     | 13.3      |
| Ash .. . . .            | 3.4         | 2.9      | 3.4       |
| Protein .. . . .        | 8.3         | 8.4      | 9.4       |
| Fat .. . . .            | 7.0         | 4.4      | 4.8       |
| Carbo-hydrates .. . . . | 57.2        | 59.3     | 56.7      |
| Fibre .. . . .          | 10.8        | 11.7     | 12.4      |

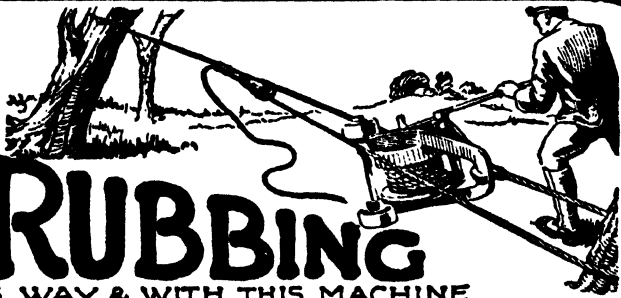

*Digestible Nutrients.*

|                            | Early Burt. | Lachlan. | Algerian. |
|----------------------------|-------------|----------|-----------|
|                            | %           | %        | %         |
| Protein .. . . .           | 6.3         | 6.4      | 7.1       |
| Fat .. . . .               | 5.6         | 3.5      | 3.8       |
| Carbo-hydrates .. . . .    | 43.5        | 45.0     | 43.1      |
| Fibre .. . . .             | 3.0         | 3.3      | 3.5       |
| Starch equivalent .. . . . | 61.1        | 58.7     | 58.3      |

When foodstuffs of the same type are to be used a calculation of their starch equivalent values allows us to compare them one with the other. For the oat varieties shown above, it can be seen that the starch equivalent values are—

|                     |      |
|---------------------|------|
| Early Burt .. . . . | %    |
| Lachlan .. . . .    | 61.1 |
| Algerian .. . . .   | 58.7 |
|                     | 58.3 |

These figures show that Algerian and Lachlan are of equal feeding value, and Early Burt is a little superior to the others.

**G GRUBBING**  
 THIS WAY & WITH THIS MACHINE  
**THE MONKEY GRUBBER**

Is the unvalued method of clearing land. Of special design, and constructed to give great power in a compact and portable unit, trees and stumps are pulled cleanly, leaving less roots and snags to run. A Rope Shortener, together with simple and complete sturdy rope fittings, make extra savings in time. Yields move up and costs come down.

**TREWHELLA BROS. PTY. LTD., TRENTHAM, VIC.**

**HORTICULTURAL INQUIRIES.**

[Replies supplied by Mr. G. QUINN, Chief Horticultural Instructor.]

**Cincturing the Currant Vine.**

Can you advise me of the early history of the introduction of cincturing the currant vine, and the correct method of doing the work? (P. H. Q., Clare.) Reply—The practice—which is age old in Greece—was introduced here by the late W. C. Grasby, when Editor of the *Garden and Field*, who visited Greece about the latter end of the nineties of last century. The accepted practice is to remove a very narrow ring of bark— $1/12$ th of an inch wide is enough—right into the sapwood layer. It is done with the best effect when the corollas—green star-shaped caps—are falling from the flowers very freely. The action on the plant is a temporary check to the returning elaborated sap, owing to the part severance and exposure to the air of the sap vessels through which this descends. The crude sap ascends to the leaves through vessels more deeply situated, and, consequently, that stream is not seriously interfered with by the operation. The narrow cincture is soon filled across with new callus cells, and the normal ascent and descent is gradually restored. In the meantime, the berries become knitted, as it were, to their pedicels, and adhere firmly when growth is resumed.

**Non-setting of Almonds.**

A member of the Smoky Bay Branch has several almond trees, and the blossoms fall off instead of setting fruit. Reply—There are several causes, either of which may account for this defect. (1) If the almond trees bloom in the frosty or cold and wet period of the year in this State—usually at the end of July and early August—the climatic effects may clog the pollen or damage the flowers, as well as inhibit the activities of pollen carrying insects. The Brandis variety is seriously influenced in these directions. (2) If only one variety is grown, the blossoms may be self sterile, or if more sorts are grown but only one sort blooms at a time, the same effect operates. (3) The planting of sorts known to bloom simultaneously is a safeguard, and more particularly if they be from mid-season to late in their periods of blossoming. Amongst soft-shelled kinds the following are recommended for inter-pollination:—Ne Plus Ultra for I.X.L.; Ne Plus Ultra for Harriott's Seedling; I.X.L., Hatch's Nonpareil, and Jordan for Ne Plus Ultra.

**DAIRYING INQUIRIES.**

[Reply supplied by Mr. H. B. BARLOW, Chief Dairy Instructor.]

**Feeding Calves for Market.**

“What is the best ration on which to fatten calves for market? Would either skim milk and pollard or crushed wheat and milk be suitable?” A.A.L., Gladstone. Reply—Skim milk and pollard makes quite a good ration for calves, but if a little linseed meal or gruel made from linseed meal is added, a better fattening ration could be made up. When using linseed meal, I suggest slowly boiling about 1lb. of linseed meal in about 3galls. of water and then feeding each calf about half a pint of the resultant gruel in its skim milk. With young calves, add the linseed gruel in small amounts to commence with and gradually increase the amount as the calf gets older. After the calves are about three weeks to one month old, it is advisable to make available some chaff and crushed grain for them to eat during the day. The grain mixture can be made up of any grains available, i.e., oats, barley, or wheat, or a mixture of each. Some people prefer adding a little bran, but if grain is available this is not necessary. It is better to feed the grain mixture in a dry state in preference to mixing it with the

milk. The main point in fattening calves for the market is to keep them in good health, and to obtain the best results they should be fed their milk ration regularly, and at approximately the same temperature each day (about 90 deg. F.), and all buckets, etc., should be kept clean and free from any sourness.

### VETERINARY INQUIRIES.

[Replies supplied by Veterinary Officers, Stock and Brands Department.]

A member of the Coonawarra Branch of the Agricultural Bureau has a cow due to calve in three weeks, the animal is still in full milk and cannot be dried off. Reply—It is highly desirable that all cows should have a rest period of from four to six weeks before calving in order that the calf may be amply nourished and born strong, and also to allow the cow to recuperate from the drain on her system, which is heavy when she is producing a lot of milk. The cow will not be dried if she is kept on green pasture or concentrates. The following routine is suggested:—Withhold all concentrates and green feed, and only feed on roughage, such as hay with very little grain in it. Do not milk the cow out completely, but leave a little milk in the vessel, and gradually reduce to milking once a day, and then once in two days, &c. Give one tablespoonful of alum dissolved in water twice a day for three or four days. The fact that the cow continues to lactate is not, in the true sense of the word, serious, but a rest period is advisable. When she calves, be on the look out for symptoms of milk fever, which often occurs in deep milking cows.

“E. H. R.,” Wudinna, asks cause of horse stamping feet before passing water. Reply—Wash out the sheath with warm water and soap, and subsequently smear with olive oil. If horse is in poor condition, it should be starved for 18 hours and subsequently given the following drench:—Raw linseed oil, 1½ pints; turpentine, 4 tablespoonfuls. Shake thoroughly before giving.

“D. F.,” Kyancutta, asks treatment for sheep that have become foundered due to grazing on wheat crop. Reply—The treatment is as follows:—Give following drench at once:—Bicarbonate of soda, two heaped tablespoonfuls dissolved in half a pint of water. Two hours later drench with raw linseed oil (½ pint) in which is mixed 10 drops of turpentine. Take sheep off wheat crop. Starve for three to four days. Allow plenty of water and a little straw. Treatment, to be satisfactory, must be adopted early.

“L. E. T.,” Bowhill, asks—(1) cure for warts on cow's teats, and (2) treatment for cow which did not pass the afterbirth until 11 days after calving? Replies—(1) Warts on teats can often be removed by washing the teats after each milking in

35, CURRIE STREET, ADELAIDE.

warm water containing a little washing soda, and then, after drying them, rubbing in a little castor or olive oil. The application of salicylic acid 1 part, collodion 7 parts, to the teats for a few days will also serve to remove them. Failing success with either of these remedies, snip off any warts with necks and touch the stumps with caustic pencil (though if they are large it would perhaps be safer to remove them by tying a ligature of silk or fine waxed thread round them). The caustic pencil can also be used to touch flat warts after washing them first in the washing soda solution and drying, but care must be taken that the caustic is applied only to the warts and not to any of the adjacent healthy skin. (2) Where retention of the afterbirth occurs after calving, steps should be taken to remove it manually long before the lapse of such a long period, otherwise the cow is very likely to get a septic metritis, which, if it does not kill her, will render her useless for further breeding purposes.

"E. M. E.," Paruna, reports aged mare with swelling on brisket extending forward between front legs, scouring badly, and off food? Reply—The following treatment is suggested:—(1) Give following powder daily for seven days—mix in small damped feed: Pulv. arsenic, 5 grains; antim. pot. tart., 1 dram; ferri sulph., 4 drams. (2) Feed on boiled oats or boiled linseed mixed in small feed of bran and chaff. Supply a little green lucerne, if available. (3) If animal will not eat, give a heaped teaspoonful of powdered nux vomica night and morning for a few days. Mix with treacle and smear on tongue.

"A. E. T.," Crystal Brook, has cow, after being fed on rusty and damp hay, is dull and listless, loss of appetite, and has lost condition. Reply—A thorough purgative action is desirable, and the following treatment is recommended:—Take Glaubers salts,  $\frac{1}{2}$  lb.; Epsom salts, 1 lb.; powdered ammonium carbonate, 1 oz.; ginger, 2 ozs.; treacle, 1 lb.; water, 2 pints. Directions—dissolve the salts in a pint of hot water, add the ammonium carbonate, ginger, and treacle, and another pint of water. Give when cool. Allow the animal plenty of water to drink. Follow with powdered nux vomica twice a day for 10 days. Dose—1 teaspoonful in treacle, or mixed in a little bran. If possible, give green lucerne and a little scalded oats.

"F. L. J.," Yandiah, reports horse with a skin disease on shoulders and neck. Reply—Try the following dressing, which should be applied after washing the affected parts with soft soap and warm water. Repeat dressing every three days for three weeks:—Take flowers of sulphur, 4 ozs.; oil of creosote, 1 oz.; olive or raw linseed oil, 1 pint. Mix and make lotion. Directions—Rub in gently as directed.

"W. A. W.," Lyrup, has cow which, although calved four days ago, has not given any milk. Front quarters of udder very hard. Reply—The condition is very probably a chronic mammitis (inflammation of the udder). It is doubtful whether treatment will be successful. The following measures can be tried:—(1) Apply hot packs to affected quarters three or four times daily. (2) After each fomentation, dry and massage gently with warm camphorated oil. (3) Strip out as often as possible during the day. (4) Keep the animal isolated.

"E. J. McL.," Caliph, reports mare with apparent weakness in bladder. When trotting or moving urine is passed, and the animal cannot raise its tail. Reply—The mare is suffering from paralysis, very possibly due to an injury of the posterior part of the spine. If the condition has been there some time and is getting worse, the chances of recovery are remote. Otherwise, put the animal out of work for three to four months. The spine could be well rubbed occasionally with a good stimulating liniment, which can be obtained from the local chemist.

The Meadows Branch reports, "heifers continually chewing pieces of stick and bark." Reply—This habit is probably due to a want of mineral matter in the feed. It is suggested that the following lick is made available for the young stock:—Sterilized sweet ground bone meal, 2 parts; coarse salt, 1 part. Put out in troughs near watering places. To make it more palatable, add a little linseed meal and crushed oats. A quantity sufficient for three to four days only should be put out at a time.

*The Fordson has pioneered power farming in Australia, and in every corner of the Commonwealth to-day is increasing crop average and lowering crop production costs.*

## Good Service for the Fordson

The Standard Fordson

**£220**

at nearest Ford works

*Price subject to Sales Tax*

*Increased crop production has been urged by the Prime Minister and State Premiers as being vital to the nation's prosperity. With the plea to grow more crops has been the call to reduce production costs. The solution is found in Fordson farming—power farming at lowest cost.*

**GOOD** Service is an important factor in the ability of the New Fordson Tractor to lower farm production costs.

Service for the Fordson is reliable and efficient *always*, and is never far away, wherever you may be. More than 1300 Ford Service Stations throughout Australia are at your command to service all Ford products—efficiently, economically and quickly.

It is this provision for quick and thorough service that has made the Fordson the choice of Australian farmers to whom delay may mean heavy loss.

In addition, the purchase price is low, the Fordson operates on either kerosene or petrol; spare parts, when necessary, are always available and their prices are standardised by the Ford Motor Company. There are standard prices, too, for all repair and service work operated under Ford factory supervision. You know in advance exactly what each repair operation will cost.

Consider this aspect well. Fordson service is *good* Service—in every way.

Call on your nearest Ford Dealer for full Fordson information and for actual figures showing its proved saving in time and money over horse-team work.

## THE WORLD POSITION OF WHEAT.

[Address by Professor A. J. Perkins, Director of Agriculture, delivered at the Forty-first Annual Congress of the Agricultural Bureau.]

### INTRODUCTORY.

"World Wheat Production: Where and When Produced," was the subject matter suggested by the Jamestown Branch of the Agricultural Bureau for an address I had been asked to deliver to its members. I must confess that at the outset I had difficulty in discovering relevant items that might reasonably and usefully be dragged within an ambit apparently so limiting. But when, on reflection, I decided that the motive behind the suggested title was in all probability the recent calamitous fall in the price of Wheat, coupled with the natural anxiety of an important Wheat-growing district as to what the future might hold in store, my embarrassment took on another shape, and I found myself wondering how much matter I dare include in my address without running the risk of wearying my audience. And to-night I must leave it to an audience of wider interests to decide whether I have succeeded in keeping the balance even between "too much" and "too little."

### THE COMMONWEALTH'S RELATIONSHIP TO WHEAT.

I take it for granted that we all recognise that apart from occasional malign influence of speculators, the price of Wheat, like that of all other commodities, is regulated by the Law of Supply and Demand; that is to say, that it rises or falls, according as one or the other is in the ascendant. I shall have occasion to show later on that the main World demand for Wheat comes from the thickly populated Continent of Europe, and that as in Europe, Great Britain is the principal importer and London the chief port of Great Britain, local prices of Wheat are usually determined by what is known as London "parity," that is to say, on prices offering from time to time in London, less costs of delivery from ports of export. These costs from Port Adelaide are represented at the present time by approximately 8d. per bushel. This, I am afraid, is cold comfort for us who neither as individuals nor as a community are of sufficient consequence to influence the market in one direction or another. And yet we have undoubtedly owed the rapid development of our farming areas almost exclusively to Wheat; and it may safely be added that our future progress as a community will very largely depend upon our ability still further to extend our Wheat fields and generally increase the mean production therefrom. Indeed, so great is the influence of Wheat on the stability of the community deemed to be that quite recently the Prime Minister made a special appeal to farmers of the Commonwealth to place maximum areas under Wheat, and supported his appeal by the introduction of Federal legislation guaranteeing a minimum price of 4s. a bushel at railway sidings, subject to certain conditions. But, on the other hand, we learn that American farmers have been strongly urged to reduce their Wheat sowings to the extent of at least 10 per cent. Clearly we have here the results of conflicting viewpoints, each of which can probably be justified on the incidence of local environment. The United States happens to be a country dependent upon its rural industries to a minor degree only, but in which farmers have available for exploitation a vast territory open to widely diversified types of farming; they have, too, the inestimable advantage of a home market represented by over 120 million people. Hence, whilst it would apparently be much to the advantage of United States' farmers if their local Wheat production could be reduced to bare requirements of this huge home market, it is difficult to see how a reduction of 10 per cent., which would still leave an exportable surplus of 100 million bushels, could benefit them to any appreciable extent. Indeed,

towards an end of this kind a reduction of quite 20 per cent. would be requisite. Australia, on the other hand, is completely dependent upon rural production for its livelihood. It is, too, a young country, still in the throes of development; nor can it afford to mark time; and finally, apart from grazing, for its development it is more or less tied down to a single type of land exploitation, involving wheat as the major item. It follows, therefore, that however great future competition of others may prove to be, it is with us a matter of national necessity that for many years to come we should continue to produce Wheat in regularly increasing quantities. It is true that in the struggle for World Markets that must necessarily follow the local farmer will at times be heavily hit; and in common fairness the man who is fighting the Commonwealth's battles should not be left to do so single-handed, and in some instances with one hand tied behind his back. The Prime Minister has indicated one way of equalising matters in this direction; but it is very far from being the only one open to our ruling powers. There are such matters as the general incidence of taxation, high cost of living, duties on plant and material essential to the production of Wheat, freights, harbor dues, good roads, &c., all matters which to-day burden the cost of Production of Wheat and its conveyance to market, and all of which admit of adjustments that would eventually lighten the load.

#### WHEAT PRODUCTION OF THE CONTINENTS OF THE WORLD.

Let us now consider what has been within recent years the Mean World Production of Wheat, together with its distribution over the Continents of the globe. Data relating to this question have been summarised in Table I., which has been adapted and expanded from Cornell University Memoir 118 (V. P. Timoshenko).

TABLE I.—*Showing Mean Pre-War, War, and Post-War Distribution of Wheat Production throughout the World.*

|                                                                                              | Pre-War.<br>1909-13.    |                       | War.<br>1914-18.        |                       | Post-War.<br>1921-25.   |                       | 1926-28.                |                       |

| Wheat available per<br>head of World popu-<br>lation after deduction<br>of seed requirements | 2.41                    |                       | 2.39                    |                       | 2.22                    |                       | 2.46                    |                       |
|                                                                                              | 1913.                   |                       | 1918.                   |                       | 1925.                   |                       | 1928.                   |                       |
| Mean Export Value of<br>Wheat in Australia .                                                 | s. d.<br>3 6            |                       | s. d.<br>4 10           |                       | s. d.<br>6 8            |                       | s. d.<br>4 10           |                       |

I shall first draw attention to the fact that of all the Continents of the globe, small but thickly populated Europe is the greatest producer of Wheat, its quota prior to the War being represented by an annual mean of 1,963 million bushels, or 43.6 per cent. of the World's total production. During the course of the War, as might have been anticipated, European mean production fell away to 1,561 million bushels, or 35.5 per cent. of World Production; thereafter its production remained more or less stationary for a period of seven years; finally, in the three years that followed

—1926-28—European mean production became normal again, although, owing to a general increase in World Production, Europe's percentage fell from 43.6 to 38.9 per cent.

It is clear, too, that during the War years and the years of settlement that followed, the other Continents made haste to make good Europe's Wheat deficiency. In this direction North America was the leader, rising from 897 million bushels, or 19.9 per cent. of the total, to 1,355 millions, or 26.7 per cent.; over the same period South America progressed from 4.0 to 5.6 per cent. of the World's production, and Australasia from 2.2 to 3.0 per cent. Africa and Asia, however, remained more or less stationary.

The net result of the position is that during the 1926-28 period World Mean Wheat Production increased by close on 600 million bushels per annum, relatively to Pre-War figures, or 12.7 per cent., whilst over the same period World population increased by 9.3 per cent. only. If, therefore, we assume Pre-War figures to represent fairly accurately World Wheat requirements relatively to population, it follows that there must have been an appreciable surplus in the 1926-28 period—approximately 462 million bushels per annum—and it is this surplus that has been mainly responsible for the drop in the price of Wheat. And since Europe is not only the largest producer of Wheat, but also the largest importer and consumer, it follows, too, that the chief beneficiaries of this recent World position have been European consumers, and the chief sufferers American farmers who, we have seen, have been officially recommended to curtail future sowings.

The position is further emphasised by a consideration of the amount of Wheat available for food after due allowance for Seed requirements in relation to World population. In this connection we may note that in Pre-War days wheat available for food was 2.41 bushels per head of population, and the mean Australian export value 3s. 6d. a bushel in 1913; during the War period there was a slight decline to 2.39 bushels, whilst prices were irregular, owing to difficulties of transport; during the seven years that followed the War there was a quite appreciable decline to 2.22 bushels, and mean export prices rose to 6s. 8d. in 1925; finally, in the 1926-28 period available wheat supplies rose to 2.46 bushels and mean export values declined in sympathy to 4s. 10d. in 1928; and since then the decline has been greater still.

Differences between figures given for Wheat available per head of population in the World may appear small in relation to their apparent influence on World prices. Nevertheless, it is a well-known fact that very small surpluses on any market suffice to bring down current prices; moreover, as there are millions of people in this world that never make any use whatsoever of Wheat, these figures would acquire far greater emphasis if they could be expressed in terms of the Wheat consumers of the World, instead of in terms of the World's total population.

#### AUSTRALIAN MEAN WHEAT CONSUMPTION.

Although I have not the means of indicating to you exactly what are the Wheat-consuming capacities of those countries that make a regular use of this cereal, purely Australian statistical data on the subject have been carefully kept and may be accepted by us as a basis for rough comparison. This question will acquire added importance when we come to consider later on the possibilities of increased consumption of Wheat in those countries in which but sparing use has as yet been made of it. According to the Commonwealth Statistician, mean figures for Australian Home Consumption of Wheat per head of population are as follows:—

|                                         | Bushels.    |
|-----------------------------------------|-------------|
| For Human Consumption . . . . .         | 5.042       |
| Fed to Live Stock . . . . .             | 0.482       |
| Used for Seed . . . . .                 | 1.806       |
| <b>Total Home Consumption . . . . .</b> | <b>7.33</b> |

Hence, in round figures, the mean yearly consumption of Wheat in Australia has been represented by 5 bushels per head of population, whilst in the neighborhood of half a bushel has been fed to Pigs and Fowls. In order to complete Australian requirements in the matter of cereal foodstuffs, it should be added that we consume in addition in the neighborhood of 6lbs. of Oats and 6lbs. of Rice per head of population. Our total cereal foodstuffs requirements correspond, therefore, to an equivalent of  $5\frac{1}{2}$  bushels of Wheat. In this connection, it should not be overlooked that we are essentially a meat-eating rather than a bread-eating people, and prone, I am afraid, to be wasteful of foodstuffs which we usually find in profusion around us. Other nationalities, on the other hand, and in particular the Latin and Semitic races, and all those whose economic circumstances do not permit of the free use of meat, consume usually a greater proportion of cereal foodstuffs than is the case in Australia. Nevertheless, if the World Population as a whole were to consume as much Wheat per head as we do, current World Wheat Production could, to all intents and purposes, be doubled without undue embarrassment to World Markets.

#### WHEAT AND ITS SURROGATES.

But, as we have already had occasion to note, not only in present circumstances is it not possible to double current production of Wheat, but of recent years the markets of the World have been embarrassed by the presence of unabsorbed surpluses, which have led to appreciable decline in prices. It is clear, therefore, that there are teeming millions in this World that secure their farinaceous foodstuffs from other sources than Wheat. It is fairly obvious in this connection that there is a natural tendency among the inhabitants of any country to live upon the produce of the land they occupy; and in earlier times, when means of communication were defective, this tendency amounted to compulsion. Under these influences, and in the course of generations, special tastes and food customs have become firmly ingrained in those people that knew not Wheat, and the latter has in consequence to-day to face the competition of substitutes of varying merits.

An examination of the general position will serve to show that whereas for centuries Wheat has formed essential part of the dietaries of Western Europe, the Mediterranean countries and parts of Western Asia, its progress elsewhere has been slow, apart from America and Australasia, both of which continents have been colonised mainly from Western Europe. Rice, it may be pointed out, continues the staple cereal foodstuff of a large proportion of Asia, including China, India, Japan, &c., and although Wheat has succeeded in worming its way in, its position in these countries is still one of relatively small importance. Maize is the chief cereal foodstuff in Southern Africa, and to a less extent has encroached upon the territory of Wheat in Egypt, and other Mediterranean countries, the United States, and parts of South America. Even at the present time Rye is more extensively used for human consumption than Wheat in Russia and Central Europe generally. Sorghum and Millet grains supply the only cereal foodstuffs available in certain parts of Africa and Asia; Barley, apart altogether from its association with liquid refreshments, is in common use for human consumption in many countries. Beans, Pease, and Pulse generally supply the same needs as Wheat, and even vegetables and fruits rich in starch, such as potatoes, bananas, chestnuts, dates, &c., may be said on occasion to prove effective substitutes. And, finally, we ourselves, convinced Wheat-growers though we be, have not hesitated, under the guidance of thrifty Scotland, to go to the stables for part of our breakfast requirements.

It will be clear, therefore, that Wheat has hitherto met and will continue to meet in the future with many obstacles to its successful expansion over the World. And, unfortunately, the World War has introduced a new obstacle in the shape of the impoverishment of many normally Wheat consuming communities, who in consequence have been thrown back upon cheaper substitutes. It may be assumed, however, that this obstacle will disappear in the course of time, with the improvement of the economic position of

those concerned, and that as a result Wheat prices will eventually show a gradually improving tendency. I am bound, however, to point out that however much we may be prejudiced in favor of Wheat as an article of diet, we cannot claim, apart from questions of tastes, which vary with every individual, that Wheat is essentially superior as a foodstuff to many of its substitutes. On a basis of Starch Equivalence, for instance, 100lbs. of Rice or Maize may be counted upon to go as far in the matter of food values as 115lbs. of Wheat or Rye. The only real advantage that can be claimed for Wheat in this connection is its relatively high contents of digestible Protein, and of the latter we usually make but little use in our anxiety to secure a perfectly White Loaf.

I shall now endeavor to show in what quantities the various cereal foodstuffs have in the aggregate been available to Man within recent times. In this connection it is necessary to note that Wheat, and particularly some of its substitutes, are not reserved exclusively for human food; a proportion of these foodstuffs goes to meet the requirements of domesticated Live Stock, and particularly is this the case of Oats, Barley, and Maize; but, unfortunately, available data are insufficient to enable us to distinguish on a World wide basis between what is reserved for Man and what is fed to Live Stock. Hence, in the Table that follows I have restricted myself to the four chief Cereals, namely, Wheat, Rye, Rice, and Maize, leaving to Live Stock the balance of the substitutes for Wheat. This arrangement will enable us to get a rough and ready appreciation of the position.

TABLE II.—*Showing Estimated Mean Total World Production (1926-28) of Wheat, Rye, Rice, and Maize in relation to World Population.*

|                                                                | Short Tons<br>(2,000lbs.) |
|----------------------------------------------------------------|---------------------------|
| Wheat .....                                                    | 152,187,000               |
| Rye .....                                                      | 49,361,928                |
| Rice .....                                                     | 92,500,000                |
| Maize .....                                                    | 126,801,623               |
| World Total .....                                              | 420,850,551               |
| Less allowance for Seed .....                                  | 123,284,500               |
| Estimated aggregate available for Human Consumption .....      | 297,566,051               |
| World Population (1928) .....                                  | 1,914,058,810             |
| Quantity of cereals per head assumed to be available .....     | 311lbs.                   |
| Equivalent to .....                                            | 5.18bushs. of Wheat       |
| Corresponding Australian figure, including Rice and Oats ..... | 5.24bushs.                |

From the above it will be clear that the World has not been in danger of starvation within recent times, except perhaps in countries in which means of distribution and communication are still more or less inadequate. It is worthy of note that the quantity of Cereal Food per head of population estimated to have been available for World consumption, namely, the equivalent of 5.18 bushels of Wheat, corresponds almost exactly to the statistically determined Australian figure, namely, the equivalent of 5.24 bushels of Wheat.

As a matter of general interest it can be added that for the same period—1926-28—the mean World Production of Oats was represented by 91,504,100, and that of Barley by 42,943,523 short Tons.

#### CHIEF WHEAT GROWING COUNTRIES OF THE WORLD.

We can now come to closer grips with the question, and consider in detail which are the countries of the World chiefly concerned in Wheat growing. The extreme adaptability of Wheat as a cultivated plant is shown by the wide range of climate and soil over which it has successfully extended. This fact may be gathered from the large number of Wheat-growing countries enumerated in Table III., and illustrated on the

accompanying map.\* These Wheat-growing countries have been placed in order of their mean total Production for the 1924-28 period, representing the latest Statistical data available at the time of writing. In addition to total production figures, the Table includes mean areas under Wheat in each country, percentages which total production in each country bears to World Production, and the mean yield per acre in each country.

TABLE III.—*Statistical Data, 1924-28, concerning Main Wheat-growing Countries of the World.*

| Other Countries . . . . .       | 30,870                         | 448,471                                  | 8.85                           | 14.53                            |
| World Wheat Production          | 362,350                        | 5,072,900                                | 100.00                         | 14.00                            |

It will be observed that within recent years the mean yearly Wheat Production of the World has exceeded 5,000 million bushels garnered from over 362 million acres, representing a general mean yield per acre of 14 bushels. There is no other cultivated crop that occupies areas of equal importance; and yet, relatively to the dry surface

\*See inset at the end of this issue.

of the globe, this vast area does not represent much more than 1 per cent.: it could, in fact, be tucked away in one-fifth of the area of Australia as has been indicated in the accompanying map, and this should lead to the belief that if in the course of time the World should require more Wheat, there would still remain ample room for expansion.

In the matter of Total Production the United States, Russia, and China, aggregating more than 40 per cent. of World Production, are a long way in the lead. Other countries of importance in this connection are Canada, India, and France, which together aggregate close on 20 per cent. of World Production; whilst Australia comes tenth on the list with 2.75 per cent. of World Production. Nevertheless, Australia has made considerable progress within recent times, and will in the course of time occupy a far more important position among World Wheat Producers. Data relative to Australia's progress as a Wheat Grower are shown below in Table IV.:—

TABLE IV.—*Australian Wheat Statistics for the Current Century.*

| Quinquennial Periods.           | Mean Areas<br>Under Wheat<br>per Annum.<br>Acres. | Mean Production per Annum. |                    | Mean<br>Population. |
|---------------------------------|---------------------------------------------------|----------------------------|--------------------|---------------------|
|                                 |                                                   | Total.<br>Bush.            | Per Acre.<br>Bush. |                     |
| 1900-04 .....                   | 5,554,949                                         | 45,595,661                 | 8.21               | 3,897,213           |
| 1905-09 .....                   | 5,867,510                                         | 66,456,338                 | 11.33              | 4,203,678           |
| 1910-14 .....                   | 8,215,684                                         | 77,393,187                 | 9.42               | 4,708,026           |
| 1915-19 .....                   | 9,640,292                                         | 113,566,708                | 11.78              | 5,051,516           |
| 1920-24 .....                   | 9,388,094                                         | 134,593,901                | 14.34              | 5,661,596           |
| 1925-28 .....                   | 12,270,137                                        | 133,297,861                | 10.86              | 6,168,560           |
| Total mean increase in 29 years | 6,715,188                                         | 87,702,200                 | —                  | 2,271,347           |
| Percentage increase in 29 years | 120.9%                                            | 192.3%                     | —                  | 58.3%               |

Thus, then, in the course of 29 years, and on the basis of means of successive quinquennial periods, our area under Wheat has more than doubled, our production of Wheat has nearly trebled, whilst over the same period the increase in our population has been slightly over one-half. And there is every reason for believing that during the next 30 years corresponding improvements will be made both in areas and in total production of Wheat. It may be anticipated that by that time Australia's Wheat contribution will be in the neighborhood of 400 million bushels, that is to say, corresponding to present-day Canadian production. This increased production will come chiefly from extension in areas sown in Western Australia and New South Wales, and from all-round improvement in mean yields per acre in all of the Wheat-growing States as a result of wider application of improved methods of farming and more thorough reclamation from scrub of existing areas.

#### WORLD MEAN YIELDS PER ACRE.

A glance at the last column of Table III. will serve to show that mean yields per acre vary within very wide limits, from 7.31 bushels in Rhodesia to 39.38 bushels in the Netherlands, the mean yield of the World being exactly 14 bushels. Now, there may be an inclination to look upon these enormous differences in yield as the natural results of good and poor farming methods respectively: and whilst there is certainly something to be said for that point of view the main limiting factor may be said to be climate. It can be said generally that those countries in which the mean growing period of Wheat is longest will in the long run secure the highest mean yields per acre. Countries such as Great Britain, New Zealand, &c., in which Winter-sown wheat takes 10 months to come to maturity will almost invariably show higher mean yields per acre than countries such as Australia, the Union of South Africa, &c., in which Wheat comes to maturity in six to seven months. At the same time, the influence of good farming methods on yields within the limits imposed by climate cannot be denied: and in this direction the more advanced countries will inevitably show up to better advantage than corresponding countries in which backward methods are in more common use. Finally, there

is the fact that in some countries Wheat growing is carried out on intensive lines and small individual areas, and in others on extensive lines and large individual areas: it is clear that other things being equal, the mean yields per acre of the former will usually exceed those of the latter, and occasionally very considerably. The Netherlands, Denmark, and Belgium have already shown what can be done in this direction.

#### INTERNATIONAL TRADE IN WHEAT.

The importance of any country on the wheat markets of the World is not, however, determined by its total production, but by the size of its mean surplus above local requirements: it is this exportable surplus which enters into International trade and alone determines the standing of the country concerned. From the latter point of view Wheat-consuming countries may be separated into two groups, namely (1) Wheat-exporting countries, which are very limited in numbers, and (2) Wheat-importing countries which are far more numerous. Data concerning these two groups have been given in Tables V. and VI., respectively:—

TABLE V.—*Mean Net Exports (i.e., Exports less Imports) per Annum, of Wheat (including Flour) of chief World Exporters (1925-27).*

|                     | Net Exports. |             | Percentages. |        |
|---------------------|--------------|-------------|--------------|--------|

| Hungary .....       | 18,351,000   |             | 2.39         |        |
| Jugo-Slavia .....   | 10,384,000   |             | 1.35         |        |
| Rumania .....       | 7,784,000    |             | 1.02         |        |
| Chile .....         | 3,181,000    |             | 0.41         |        |
| Bulgaria.....       | 1,579,000    |             | 0.21         |        |
| Tunis .....         | 1,056,000    |             | 0.14         |        |
| Algeria .....       | 871,000      |             | 0.11         |        |
| Spain .....         | 279,000      |             | 0.04         |        |
|                     |              | 89,196,000  |              | 11.63  |
|                     |              | 766,890,000 |              | 100.00 |

It should be observed that during the 1925-27 period the mean quantity of Wheat available for international trade was represented by 766,890,000 bushels per annum, and that towards this total four countries contributed over 88 per cent. of the World's requirements. Among these four countries Australia occupied the fourth position, her export quota representing 13 per cent. of the World's net export trade, whereas her total production represented 2½ per cent. only of World production. If in 30 years' time Australia's Wheat Production should, as I anticipate, attain to 400 million Bushels and her population to 10 millions, our Wheat Export surplus should then be in excess of 325 million bushels; that is to say, a quantity greater than Canada's present day export surplus. We should by that time occupy a commanding position on the markets of the World. It can be added, on the other hand, that the rapidly expanding population of the United States points to the probability that the latter country will eventually withdraw from the ranks of exporters, in which case she would probably be succeeded by Russia.

Consideration can next be given to the requirements of the chief Wheat Importing countries of the World.

TABLE VI.—*Mean Net Imports (Imports less Exports) per Annum, of Wheat (including Flour) of the chief importing Countries (1925-27).*

|                                 | Net Imports. |             | Percentages. |        |

| Sweden . . . . .                | 7,767,000    |             | 1.01         |        |
| Poland . . . . .                | 7,475,000    |             | 0.98         |        |
| Denmark . . . . .               | 6,356,000    |             | 0.83         |        |
| Norway . . . . .                | 5,918,000    |             | 0.77         |        |
| Cuba . . . . .                  | 5,896,000    |             | 0.77         |        |
| Union of South Africa . . . . . | 5,636,000    |             | 0.74         |        |
| Finland . . . . .               | 4,648,000    |             | 0.61         |        |
| New Zealand . . . . .           | 2,917,000    |             | 0.38         |        |
| Syria and Lebanon . . . . .     | 2,404,000    |             | 0.31         |        |
| Latvia . . . . .                | 1,720,000    |             | 0.22         |        |
| French Indo-China . . . . .     | 1,109,000    |             | 0.14         |        |
| Estonia . . . . .               | 901,000      |             | 0.12         |        |
| Ceylon . . . . .                | 871,000      |             | 0.11         |        |
|                                 |              | 229,738,000 | —            | 29.96  |
| Other Countries . . . . .       | —            | 73,060,000  | —            | 9.53   |
| Total Net Exports . . . . .     | —            | 766,890,000 | —            | 100.00 |

Again, as in the case of Net Exports, we may note that the major portion of Net Imports was absorbed in the 1925-27 period by a small number of nations. In this connection, five European nations received over 60 per cent. of the World's exportable Wheat, and among these Great Britain and Ireland received close on 30 per cent. As to the balance, 17½ per cent. went to other European nations, 12½ per cent. to other parts of the globe, and 9½ per cent. to unspecified countries. It must be clear, therefore, that in existing circumstances, Europe, and Great Britain in particular, must continue the determining factor in the matter of Wheat prices, so long as the available surplus is slightly in excess of the demand.

#### WORLD WHEAT CONSUMPTION.

We are now in a position to show what have been in recent years the consumption and wheat requirements of the Continental Divisions of the globe:—

TABLE VII.—*Summarising Apparent Wheat Consumption of the Continental Divisions of the Globe (1924-28).*

|                                      | Local Production.       |                            | Net Imports (+)<br>or<br>Net Exports (—) |                            | Local Production,<br>Plus Imports,<br>Less Exports. |                            | Wheat Apparently Available<br>for Consumption,<br>after Deduction of Seed. |                            |                                 |

It will be observed in this connection that the European apparent consumption of Wheat has been represented by 50 per cent. of the World's total production, or over 51 per cent. of the total apparently available for human consumption after deduction of seed requirements. European mean consumption per head of population (4.91bush.) is also higher than that of any other Continental Division. Second in importance in relation to quantity of Wheat consumed is Asia with its teeming millions, and third, North America: the remaining Continental Divisions—South America, Oceania, and Africa—absorb in the aggregate  $7\frac{1}{2}$  per cent. only of World Wheat available after deduction of normal seed requirements.

#### WORLD WHEAT-HARVESTING MONTHS.

Related to the vicissitudes of marketing Wheat is the particular time of the year when it became available for sale. In this connection, it is worth noting that, so varied are the climatic conditions under which Wheat is grown that there is no month in the year in which Wheat is not harvested in some part of the World or other. This point may be illustrated by the following brief summary:—

##### *January:*

New Zealand, Tasmania, Argentina, Chile, Uruguay, &c.

##### *February and March:*

India, Upper Egypt, Abyssinia, &c.

##### *April:*

Turkey, Persia, Syria, Mexico, &c.

##### *May:*

China, Japan, Syria, Lower Egypt, Florida, &c.

##### *June:*

Spain, Portugal, Greece, Italy, Algeria, Tunis, Morocco, California, &c.

##### *July:*

France, Austria, Hungary, Rumania, Southern Russia, Poland, Lower Canada, Minnesota, Colorado, &c.

##### *August:*

Britain, Belgium, Holland, Germany, Poland, &c.

##### *September and October:*

Canada, Northern Russia, Sweden, Scotland, &c.

##### *November:*

Peru, parts of South Australia, &c.

##### *December:*

Australia, Argentina, Chile, Burmah, &c.

But as exporters of Wheat we are interested not so much in harvest dates of Wheat-growing countries in general, as of those with definite exportable surpluses. In this connection it is a matter for congratulation that these exportable surpluses should be found distributed both in the Northern and the Southern Hemisphere: it follows that new wheat does not flood the markets of the World to the same extent as would otherwise have been the case. If we revert back to Table V. we shall see that out of 767 million bushels of net export Wheat, 523 millions come from the Northern and 244 millions from the Southern Hemisphere, that is to say, 68.2 per cent. and 31.8 per cent. of the aggregate total respectively: hence, it can be stated roughly that one-third of the exportable World Wheat becomes available in the first half of the calendar year, and two-thirds in the second half. And, although as denizens of the Southern Hemisphere our Export Wheat is more or less influenced by the abundance or deficiency of the preceding harvest in the Northern Hemisphere, it is much to our advantage that we should be in direct competition with one-third of the World's export surplus rather than with two-thirds. It is to be anticipated, however, that with the extension and improvement of Wheat growing both in Australia and South America, coupled with

the increased consuming requirements in North America, the relative proportions between the respective surpluses of the Northern and Southern Hemispheres will eventually be more nearly equalised.

In so far as we personally are concerned our immediate rivals are Argentina, India, and Chile: of the latter, Indian wheat becomes available earlier, and Argentine and Chilian Wheat slightly later than Australian Wheat.

#### CONCLUDING REMARKS.

And lastly, we come to a consideration of what the future may have in store for us as Wheat Growers. I have already indicated that recent supplies have outstripped demands to the extent of bringing the market value of Wheat below costs of production; at the same time I have expressed the opinion that possibilities of future progress in the Commonwealth are intimately related to our ability to extend our Wheat Fields and expand the mean production therefrom. No doubt these two propositions may appear to be more or less at variance one with the other; nevertheless, given the will, it is not impossible to reconcile them. In the first place, one of the reasons of the temporary glut in Wheat on the markets of the World, is the War impoverishment of many countries, and their inability to pay its price, with the result that many normal consumers of Wheat have had to fall back upon cheaper substitutes. It is fairly certain that the fall in price that has been the natural consequence of the glut, may prove a blessing in disguise and lead among normal Wheat consumers to a more extensive use of Wheat than has recently obtained, and eventually to a healthier tone on the markets of the World. I indicate below in Table VIII. a few examples of the cereal consumption of various countries with a view to stressing the fact that even in normally Wheat consuming nations there are still many substitutes to be displaced.

TABLE VIII.—Showing Estimated Apparent Cereal Consumption per Head of Population of a Few Typical Countries.

| Union of South Africa ..... | 105 | 6  | 1  | 366 | 478 | 7.97  |
| Brazil .....                | 54  | —  | 31 | 227 | 312 | 5.20  |

It should be observed that figures given in Table VIII. setting out cereals apparently available for human consumption in various countries are only approximately correct: it is clear that in many instances portion of the quantities shown to be available is actually consumed by Live Stock. This is particularly the case for Maize, although due allowance has been made for this fact in the case of the United States, from which comes about 75 per cent. of the World's Production.

Of the three Cereals that are shown to be in active rivalry with Wheat, we may anticipate that Rye will prove the easiest to overcome: towards that end, general improvement in the economic position of the World, and of Europe in particular, should do much. It seems probable, too, that eventually the resistance of Maize will not prove insuperable. Rice on the other hand, apart from its adaptability to conditions obtaining in those countries in which it finds readiest acceptance, derives its greatest strength from the inertia of the East: nor in these countries is it likely to decline to the position of a secondary cereal: not in our times, at all events. Notwithstanding these facts, it is certain that the gradual penetration of Western ideas and customs into the East, will have the effect of opening the way to Wheat, even in these most conservative of countries.

And, finally, let me stress the fact that although in the main it is the aim of the Nations of the World to maintain themselves from the products of the land they occupy politically, the modern tendency towards industrialisation is such that they are failing to do so in ever-increasing numbers. Hence, in modern times, the importers of essential foodstuffs, and particularly of Wheat, are many, whilst corresponding exporters form part of a gradually diminishing band. Modern hygiene, on the other hand, and modern control of Law, have led to so unprecedented an expansion in World population, as to fill with dismay economists and other pessimists, who have painfully visualised gradual World starvation in no distant future. And should these jeremiads eventuate—although I fear we shall not be there to verify them—Australia would be among the last of those happy few whose destiny it is to feed the hungry of other lands: and since charity usually begins at home, Australians, subject to adequate defensive measures, should be among the last to starve.

Again, it is an unfortunate fact, but nevertheless a well-established historical fact, that the isolated food producers of the World have always paid tribute to the organised fighters and urban communities who have found something more profitable to do than primary production; and to the extent that Wheat-growers are unable to-day to collect costs of production, they may be said to labor to-day under the same disabilities as their predecessors of past ages. We are sometimes told that Wheat can be grown cheaper in Australia than anywhere else in the World. It would be interesting to know who was first responsible for this statement; whether it was made some fifty years ago, or whether it is a present-day fiction. If we place no money value on the Labor and sweat of farmers and their families, if we overlook the tariff and other obstacles that hamper primary production throughout the Commonwealth, the theory of the cheapness of local primary production would probably be true, but not otherwise. In the matter of Wheat we have certainly had to face within recent years prices that do not meet mean costs of production; and yet we cannot give up producing Wheat. And in the absence of relief from other quarters, wheat-growers are thrown back upon themselves, and the only weapons within reach are maximum production per acre, and highest quality in sample delivered that soil and season permit of, coupled with judicious association of all possible farm side lines, and in his own interests and in those of the State, such should be the aim of every good Farmer.

## POSSIBILITIES OF THE SOUTH-EAST.

[An address delivered by W. J. SPAFFORD, Deputy Director of Agriculture, before a public meeting at Naracoorte on November 13th, 1930.]

In the light of present experience it appears that the possibilities of the South-East of South Australia all lie in the direction of agricultural development, and as the principal requirements of agriculture—climate, soils, and water supply—are all particularly favorable for rural production, the prospects of great progress being attained are very bright.

## CLIMATE.

The climate is essentially of a *temperate* character, with temperatures sufficiently low to enable it to be described as “cool.” The district receives an average rainfall varying from a little over 19ins. per annum at the northern end to about 35ins. per annum in the southern portions, and although a high proportion of the rain falls during the winter, on the whole the distribution throughout the year is good, and as a consequence all crops suited to temperate climates can be successfully grown in those parts of this country where the soils are sufficiently fertile.

## SOILS.

In such an extensive tract of country it is natural to expect to find several different types of soil, and the kinds which occur are represented by (a) *heavy-textured black and grey silts*, (b) *volcanic loams*, (c) *peats*, (d) *greyish loams*, (e) *chocolate-colored heavy loams*, (f) *stony land*, (g) *sands*. The *silty soils* are found on the low-lying flats between the ranges of hills, and mostly possess high fertility, but because of their location, most of them are too wet to be brought under cultivation, and will remain so until more drainage work has been undertaken. When adequately drained these *silts* produce heavy crops of cereals, roots, forage, and pastures. The *volcanic soils* are also very fertile, and suitable for most temperate-climate crops, and are naturally well-drained, and of such light texture that they are easily worked. *Peaty soils* are not seen in very large areas, but are to be found in many parts of the district, and in the aggregate total a fairly considerable area. When adequately drained these *peaty soils* will produce heavy root crops, and will grow forage and pasture plants luxuriantly. The *greyish loams* are to be found wherever Red Gums develop into large trees in this part of the State, and in practically all cases they rest on impervious clays fairly close to the surface. Subterranean Clover grows particularly well on these soils, provided that plenty of phosphatic fertiliser is applied to the crop, and the plant yields such a bulk of high-class fodder that this land can be profitably devoted to livestock farming. The *chocolate-colored soils with heavy texture*, to be found on some of the flats, although sour, are otherwise really fertile, and when properly cleared and sweetened, should produce very heavy crops, particularly of cereals and grasses. There is a fair amount of *stony land* in the district, and some of the stone is in such large sheets that the land is quite unsuitable for agricultural purposes, whilst in other places where the stone is not so plentiful, particularly in the high land, it can be used for cereals and pastures. Nearly all of the *sandy soils* are of a whitish color, and of low agricultural value, but they have proved suitable for the growth of the Remarkable Pine and Broad-leaved Wattle, and under present conditions are better adapted for the production of timber and wattle bark than ordinary farm produce.

## WATER SUPPLY.

In most parts of the country water of sufficiently good quality to be used for household purposes is to be obtained at shallow depths, and even in the few places where ‘ho

## PIGS.

The keeping of pigs becomes a necessity when dairying is being practised, but to enable us to make profitable progress with pig-raising on a large scale, we will have to develop an export trade in pig products of first-class quality. When this has been attained, we will probably do as the other exporters of the best pig products, i.e., use *Large White boars* to produce the ideal side of bacon required in large quantities by Great Britain.

## POULTRY.

Poultry do well in the South-East, and as an export trade has been worked up for eggs, there is every reason why this industry should be developed. The proximity of the South-East to Melbourne should make it possible for the rearing of table poultry to prove highly profitable.

## CROPS.

The natural conditions obtaining in this part of the State so favor the production of a large assortment of crops that it must always be an important producer of crops for human consumption.

*Wheat.*—At present wheat-growing is the third most important rural activity of the South-East, and the area under this crop will become greater and greater as reclamation is pushed on. Because it is so readily saleable there is always this strong incentive to grow wheat wherever it is possible, and with the clearing of land in the northern end of the district, and the drainage of the silty flats, this crop will be encouraged.

*Barley.*—Such high yields can be secured from barley that it will always be a prominent crop in the district, and when livestock farming is the rule the grain will be of greater value.

*Potatoes.*—Only about one-half of the potatoes required in the State are grown here, and there is plenty of suitable land in the South-East to more than supply our requirements of this foodstuff.

*Vines.*—There are very few crops which return so much of the cost of production to labor as does the growing of grapes, and there are large areas in the South-East suitable for the production of good-quality wines. When the fear of prohibition dies down there will, in all probability, be an increase in the area under vines.

*Sugar Beet.*—Cheap sugar of good quality is produced from sugar beet, and much of the South-East is suitable for the production of the crop. This particular crop demands such good work that the agricultural operations of all districts where it has been introduced have been much improved.

*Berries and Nuts.*—The plants producing berries and nuts usually result in high money returns per acre, and most of these crops can be successfully grown in the district. This particularly applies to such crops as strawberries, almonds, and walnuts.

*Tobacco.*—It appears that there is quite a fair chance of the tobacco crop proving successful in some parts of the South-East. If this proves to be so, the introduction of the crop will lead to big money returns being secured, and an improvement to farming practices in general in those districts where it is successful.

*Irrigation.*—The underground water is so good, and is found at such shallow depths in most parts of the district, that the possibilities of irrigating crops must not be neglected. Extremely heavy yields of most temperate-climate crops can be expected, and the use of a little extra water in the summer months will enable a number of summer-growing crops to be successfully produced, where they are a little doubtful at present. Such crops as Maize, Sorghum, Mangels, Turnips, Lucerne, &c., can be produced for a certainty with a little added water.

*Phosphates.*—Success with all crops, whether they be annuals or long-period crops, is dependent on liberal applications of phosphatic fertilisers, to nearly all soils of the South-East. Most crops warrant dressings approaching the equivalent of 2cwt. Superphosphate per acre per year, and some can do with a good deal heavier dressings.

## THE PROBLEMS OF THE "OFF" YEAR IN APPLE CULTIVATION.

*[Paper read by Mr. H. N. Wicks, Balhannah, Vice-Chairman Advisory Board of Agriculture, at the Forty-first Annual Congress of the Agricultural Bureau.]*

Apple production within the Commonwealth has grown during the last few years to such an extent that it now holds a very important place in the production of wealth. With the growth of the industry there came the increase in pests and natural enemies of the apple, which, of course, have, and will increase proportionately as the industry grows.

Being a young country, our present list of pests and diseases is a very formidable one indeed, but, nevertheless, is very small compared with some other parts of the world where apples are grown as a commercial proposition. With the coming of these pests also came the knowledge with regard to the control of same, so that at the present time, thanks to the scientist and chemist, there are few, if any, diseases or pests which the commercial apple grower would admit were of such significance as to warrant the abandonment of his business of apple production, and yet it is only a few years ago when orchards of considerable size in South Australia were grubbed up and destroyed, owing to the belief that the codlin moth was destined to make apple production an utter impossibility. The chemist, the entymologist, and the scientist combined have not only exploded this belief, but have given us—with the help of the engineer—machinery and formulas which have enabled the business to develop to its present dimensions in a very few years. It would seem, therefore, that we are at least not retreating in regard to our warfare on the pests and diseases which trouble our trees and fruit, but, nevertheless, endless care and watchfulness are necessary to success, which means, of course, endless expense of time and money.

To recuperate this time and money by putting the fruit on an unprotected market overseas in competition with fruit from all over the world is quite a problem, and the net returns from apple culture during the past few years have diminished very considerably.

The query then arises, "How are we to continue fighting these pests and continue to make a profit, especially if, as I have already stated, the pests are likely to increase rather than diminish?" The answer is, "Produce more apples from the same areas under cultivation," and this brings me to the real aim of this paper. I am quite aware that under certain conditions increased crop production, as regards apples, may be affected by varying our pruning methods by better cultivation in dry years, &c., but it is not my intention to dwell on these matters, but to suggest some avenues of investigation which I consider well worthy of very deep and careful consideration, in view of the facts which I have so far collected.

The problem of the "off" year in apple growing, in this State at any rate, is a very real one, and innumerable theories relating to pruning, &c., have been brought forward, but we are still under the influence of the alternation of the good and bad season, which during recent years have been most regular, and which have resulted in little or no export surplus every other season. That this is no good to any business needs no emphasis, especially when it is considered that we have recently adopted distinctive labels for our State, and the majority of the South Australian fruit is readily and easily distinguishable on the overseas market, and, I am glad to say, is making a very real name for itself as regards to quality. It will be very apparent

that this reputation will be very seriously discounted if we cannot keep up a continuity of supplies. Let us look at it from the buyer's point of view. Suppose we, as fruit-growers, purchased an excellent brand of spray which gave us eminent satisfaction for a specific disease, we would naturally turn to that particular brand every year; but if we found that we could only get it every two years, then, rather than keep changing over, we would adopt another line, the best possible which would give us a continuity of service. This is exactly what is happening over the other side with regard to our apples. It will then be apparent that for the time being it will probably pay us to study this problem of "off" seasons very carefully, and leave no likely avenue of investigation unexplored. The necessity for continuity of cropping is realised by practically all orchardists, and in numerous cases the practice of burning off the blooms is resorted to. This, to my mind, is a very extreme measure, and, apart from possible injury to the trees, is very evidently fundamentally wrong, because it still gives an entirely off season to the treated trees, and does not supply continuity.

Before Manurial Treatment.

During my experience as a nurseryman, which extends over a period of 25 years, during which time I have almost exclusively specialised in the propagation of deciduous trees only, I have had an opportunity of studying the natural habits of trees during the whole year through, and in quite recent years since concentrated nitrogenous manures have been procurable for stimulating growth, some remarkable facts have made themselves apparent, and it is to these that I wish to draw attention.

Some few years ago I found that an application of nitrogenous manures would, under certain conditions and given enough moisture, stimulate root growth as early as the end of May. That apple roots are not dormant for more than about three weeks during any normal season has been common knowledge for years, and although underground growth is apparent in mid-June on nursery stock, and also on bearing trees, the growth is, under ordinary conditions, small and insignificant. Bearing this in mind, I have tried dressing the orchard with nitrogenous manure during May, and

whether the manure was responsible or not I am not able to state, but the fact remains that the "off" season was not by any means bare and quite a nice picking of fruit resulted. This has happened for two "off" seasons in succession (twice in four years). It would seem that if the root system of an apple can be so stimulated in May as to make rapid growth, the vitality so collected must go into the buds, there being no leaves to absorb any of the sap, and that this is so is borne out by my experience. This brings us to a critical point which I am quite unable to answer—"When does an apple bud finally decide to produce fruit or leaves, as the case may be." This should be the first avenue of investigation in this vast question, and no doubt can be solved.

However, to continue with some of my investigations. This season, on the 20th of May, I dressed a patch of yearling nursery stock with about 3cwt. of sulphate of ammonia to the acre. The result was phenomenal, and by the end of June a mat of

After Manurial Treatment.

young growth was visible, and some of the young rootlets, which were quite white and as tender as possible were over 7in. in length. I would also like to point out that there was practically no rain during the period mentioned, although, of course, in our district there is always a certain amount of moisture available.

The usual practice with regard to the application of nitrogenous manures is to apply same in the early spring. This will help the fruit as regards size and possibly color, stimulate the tree, and enable it to carry its crop without suffering too much. The latter is very necessary to successful apple culture; nevertheless, to my mind, it is essentially and completely utilised on the fruit and foliage being produced at the time of application, as it is a quick acting manure. I do not wish for one moment to decry this practice of spring manuring, but, on the other hand, cannot too highly recommend it. Is it possible that we have taken things too much for granted in this connection, and expect a prolonged service which we will never get from one application of nitrogenous manure?

Having proved beyond question that root development on apple trees can be stimulated into very active operation during autumn by artificial means, it would seem to me that this growth must perforce assist bud development which takes place during the late autumn and winter months. Whether it can be made to assist bud development to the extent of producing fruit in the following year, I cannot definitely state, but this paper is written to ventilate the matter, and, personally, I think that there is, right here, an avenue of investigation which should not be ignored. I have very little doubt but that the crops of the ensuing year can more or less be affected by the application of the right manure during the autumn.

It would appear, therefore, that at least two points could and should be solved; firstly, the actual time of the season when apple buds turn to fruit buds or leaf buds, as the case may be, and secondly, the definite effect of heavy dressings of nitrogenous manures during autumn in the most important apple districts of this State. It would be necessary to extend these operations into several districts, and not confine them to any one area. Knowing only too well what it means to grow apples for a living, I have no hesitation in stating that the job is certainly not one for the individual grower, because the necessary time is not at his disposal, but as any investigation which might tend to increase or improve our output is vital to the State's welfare, I think that our Government might very well be asked to undertake investigations in this connection.

It was essential for the grower to seek the assistance of the scientist in the conquest of the codlin moth and other diseases, because unassisted the grower was doomed to failure. Similarly we must now appeal to the scientific worker to help us solve the greatest problem, we, as apple growers, have to face at the present time.

#### SOME OTHER AVENUES OF INVESTIGATION.

The systematic thinning both of spur wood, cluster buds after bud formation and fruit after setting, especially the latter, should be tried out thoroughly. I am of the opinion that great good may result from a heavy thinning of fruit when an excessive crop has set, and the advantage of this avenue of control would be very definite, although, possibly, costly as far as the actual labor is concerned. Providing the fruit is thinned at any time up to the period when the young fruits are as large as cherries, I feel certain that some measure of relief with regard to the off season would result. That this is so is borne out by the fact that this method of control is extensively practised by some of the leading orchardists of the Commonwealth. One of the largest growers of Western Australia, considers thinning to be one of the season's operations of just as much importance as pruning or spraying, and the results obtained from this orchard are positively astounding with regard to regularity of cropping. Then there is the matter of stock relationship to the tree. In Australia we have adopted the Northern Spy root stock almost entirely for the basis of our commercial orchards because of this stock's immunity from woolly aphis, and because of its thrifty habits and general hardihood, but as to its actual effect upon the tree itself we know nothing. As a fruiting tree, however, the Northern Spy is notoriously shy until matured in years and then is given to alternate cropping. Whether working an intermediate variety between the Spy and the tree itself would help us in solving this problem of off seasons I do not know, but certainly think it is an avenue worth exploring. That, under certain conditions, the stock has a very definite effect upon the tree, and that some of the characteristics of the former are transmitted to the latter is an established fact. An examination of the Cherry section of the stock testing experiments which have been conducted at Blackwood will prove that the stock transmits some of its characteristics to the tops with regard to growth, &c., and no doubt the crop records show that there is a great variance in crop results from

one variety on the several stocks under test. I have previously mentioned the matter of working an intermediate variety between the stock and the tree itself, and just to prove how a small intermediate variety will affect the top I will quote the instance of certain varieties of pears which will not unite with the quince stock. As most of you are aware, the cropping qualities of some pears are re-stimulated considerably by placing same on quince stock, and this stock is used extensively for these varieties. Amongst those in this class is the Glou Morceau, which in some districts is notoriously shy on pear root, but crops heavily and regularly on quince root. Now if we take a Duchess Pear and endeavor to propagate direct on to the quince, failure will result, as the tree will die within a few years. However, if we place a Duchess bud into a Glou Morceau tree, which is on a quince root, the Duchess will thrive even if, after cutting the Glou Morceau away to the bud of the Duchess, there is only an inch of Glou Morceau wood left, this will suffice to enable the Duchess to thrive and live to a ripe old age. I mention this merely to stress the influence of stock and intermediate varieties and to urge experimental work in this direction.

The above mentioned are avenues which so far have not been exploited to any extent whatever, and, if it will not be considered presumption on my part, might I be permitted to make the following suggestion:—As certain of the sections of the Blackwood Orchard will perforce cease to be of value for any purpose whatever very shortly, as they have just about completed their natural life, namely Peaches, some of the Plums and Apricots, could not the ground which these will vacate be used for carrying on some of the tests outlined here? The necessary land, plant, and equipment to a large extent is available. I consider that the good work already done at Blackwood could be still further augmented to the betterment of the industry generally.

# NINTH ANNUAL REPORT OF THE TURRETFIELD DEMONSTRATION FARM (1929-30), INCLUDING DE- TAILED ANALYSIS OF MEAN FARMING COSTS (1921-30).

[By ARTHUR J. PERKINS, Director of Agriculture.]

(Continued from page 342).

## WHEAT GROWING COSTS AT TURRETFIELD.

### A. WHEAT SOWN ON BARE FALLOW.

Essentially the farmer is interested in Wheat Growing Costs from the standpoint of Costs per Bushel; the latter, on the other hand, are dominated, in the main, by the mean yields per acre obtained in any given season. These mean yields are controlled by three factors, namely:—

- a. The special characteristics of the soil;
- b. Seasonal conditions; and
- c. The relative skill or good fortune of the farmer in making the most of these conditions in any given season.

In the tables that follow, wheat growing costs incurred have been indicated on both a per acre and per bushel basis, and, as will be seen in the summarised statement of Table XI., whereas variations in Costs per acre above or below the normal mean are relatively slight, they are very pronounced in the matter of Costs per Bushel.

TABLE XI.—*Summarising Per Acre and Per Bushel Costs of Growing Wheat sown on Bare Fallow over eight consecutive seasons.*

| Seasons.           | Areas<br>Harvested.<br>Acres. | Mean Yield<br>per Acre.<br>Bush. | Mean Costs.          |                      |

|                    |                               |                                  | Per Acre.<br>£ s. d. | Per Bushel.<br>s. d. |
| 1922-23 .....      | 202.53                        | 15.08                            | 4 1 7                | 5 5                  |
| 1923-24 .....      | 144.08                        | 9.93                             | 4 6 4                | 8 8                  |
| 1924-25 .....      | 349.32                        | 23.91                            | 4 11 1               | 3 10                 |
| 1925-26 .....      | 260.22                        | 23.42                            | 4 19 2               | 4 3                  |
| 1926-27 .....      | 369.06                        | 19.33                            | 4 14 7               | 4 11                 |
| 1927-28 .....      | 293.18                        | 21.27                            | 5 7 10               | 5 1                  |
| 1928-29 .....      | 407.56                        | 18.38                            | 5 1 6                | 5 6                  |
| 1929-30 .....      | 186.67                        | 17.47                            | 4 0 8                | 4 7                  |
| 1922-30 means .... | 276.58                        | 19.46                            | 4 14 8               | 4 10                 |

These figures make instructive reading with Wheat at 2s. a bushel at country railway sidings. Not even in our most favorable season—1924-25—when the mean yield from 350 acres was approximately 24bush. per acre, would present prices have balanced costs of production at Turretfield, which were 3s. 10d. per Bushel on the farm, or, say, 4s. delivered at the Railway siding. Actually, however, over the eight consecutive seasons mean costs incurred have been at the rate of 4s. 10d. a bushel for a 19½bush. Harvest. In this connection, the Manager is to be congratulated on the fact that in the 1929-30 Season mean Costs per Acre were reduced to £4 0s. 8d. per acre, the lowest figure in the whole series. Costs per bushel were naturally conditioned by the mean yield per acre

—17½bush.—and reached 4s. 7d. per bushel, which compares more than favorably with 5s. 5d. for a 15bush. Harvest in 1922-23.

The influence of Mean Yields per Acre on Costs of Production per Bushel may be illustrated by the following points:—

1. Over eight consecutive seasons mean Wheat yields per acre varied from 9.93bush. to 23.91bush., with a general mean for the eight seasons of 19.46bush. Hence variations in yearly mean yields took place within a range of 22.9 per cent. above the mean of the eight seasons and 49.0 per cent. below it.

2. Over the same period Mean costs per acre of growing Wheat varied from £4 0s. 8d. to £5 7s. 10d., with a general mean for the eight seasons of £4 14s. 8d. Hence, yearly variations were within a range of 13.9 per cent. above the mean of the eight seasons and 14.8 per cent. below it.

3. Finally, over the same period Costs per Bushel varied from 3s. 10d. to 8s. 8d.; hence yearly variations were within the wide range of 79.3 per cent. above the mean of the eight seasons and 20.7 per cent. below it.

As I shall have occasion to show later on, the good farmer is powerless to control costs of production, apart from his skill to make the most of what opportunities the season happens to offer; and the facts summarised above would appear to stress the fact that one of the most obvious means of meeting rising costs of production is to aim at maximum yields that circumstances permit of. It is, of course, true that seasonal factors are usually at the back of both lean and bountiful harvests, and that the farmer is no more able to control them than he is able to control the unseen economic forces which cripple his best efforts. Ultimately, however, the success of the year's operations is very closely related to the extent to which the farmer adheres to those practices which experience has taught him to be best adapted to the district in which he is placed, and on this adherence will depend the mean yield which he garners in at harvest time.

In Table XII. below I have summarised in detail the main items entering into the costs of growing Wheat at Turretfield. This Table consists of three parts: in the first part actual costs incurred in growing and harvesting 186.67 acres of Wheat in 1929-30 have been analysed in close detail. The respective percentages of the items have also been indicated in contrast with corresponding mean percentages for the 1922-29 and 1922-30 periods. In the second part of the Table the figures have been calculated on a per acre basis, and in the third on a per bushel basis, for the 1922-29 and 1922-30 periods respectively only.

From the above statements it will be noted that over a period of eight successive seasons mean inclusive Costs of growing Wheat at Turretfield have been represented by £4 14s. 8d. per acre, or 4s. 10d. a bushel for a 19.46bush. harvest. In the absence of any other authoritative statement as to costs actually incurred in growing Wheat in Australia, these figures have received special attention within recent times, and particularly so since the calamitous fall in the price of Wheat. If it costs 4s. 10d. a bushel to grow a 19.46bush. crop, how can farmers be expected to continue on the land with Wheat at 2s. a bushel and the State mean yield at 10bush. to 12bush. per Acre? In the circumstances, and in order to obviate a possible misuse of the Turretfield figures, I propose stressing here what they actually represent, and what conclusions can legitimately be drawn from them of State-wide relevancy.

In the first place, economic conditions obtaining at Turretfield are very far from typical of corresponding conditions on the average Australian Farm. The Turretfield Farm is managed by a paid Manager and all manual operations of the farm are carried out by hired labor, paid at the standard rate of wages. These conditions correspond to those obtaining on a Station property owned by a Company and worked by a hired Staff, but not to those obtaining on the average Australian Farm. The latter is usually managed by the owner, and in the majority of cases farm manual operations are carried out almost entirely by the owner and his family; in exceptional cases only 25 per cent. to 50 per cent. of the manual operations might fall to hired Labor.

Another difficulty already referred to earlier in this report (see page 337 of November issue of the *Journal of Agriculture*) is the fact that in these accounts Turretfield is assumed to be a leased property upon which regular annual rent is paid, the value of which is distributed among the various accounts concerned. Most South Australian Farms are freehold properties, or Crown Leases on a covenant to purchase, completion of which extends over a long period of years. In such circumstances, charges for rent, or what corresponds to the same thing, interest on Capital invested in land, would be correspondingly lower on the average farm than at Turretfield. Similar in nature is the fact that the money value of Turretfield land is higher than that of the average South Australian freehold Wheat Farm.

Again, the soil of the Turretfield Farm is exceptionally heavy, and as such is relatively costly to till; hence the cost of Tillage Operations on the average Mallee Farm will be considerably less than the Turretfield mean figure of 19s. 9d. per acre.

And, finally, at Turretfield Wheat Growing is associated with a Fat Lamb Flock of Sheep, which as a rule grazes over the equivalent of one-half of the area of the farm. It follows, therefore, that at Turretfield the Wheat crop is relieved of a considerable proportion of the rental value of the land, whereas on a farm on which Working Horses and the family cow only had access to available grazing areas, the year's Wheat Crop would have to carry the full cost of the rental value of the whole farm.

The above difficulties represent the main reasons why the Turretfield figures cannot safely be assumed to have State-wide significance, except subject to limiting reserves, even on the basis of costs per acre; and when costs per bushel are in question, differences in mean yields complicate the position still further. Bearing in mind these difficulties, let us examine what conclusions of value we may derive from the figures.

In the three Statements of Table XIII., I have described those costs as "Inclusive Costs," i.e., every item has been debited against the Wheat Crop that legitimate accounting permits of. In this connection it should be pointed out that this practice is not altogether in keeping with the views of the majority of English Economists, who apparently would exclude from Costs of production interest on the Farmer's Capital, unpaid family Labor, &c. These views, which I cannot accept as legitimate, would reduce the cost of growing Wheat at Turretfield to 4s. 6d. to a tenant-farmer with a paid Staff, or to 3s. 3d. if he used no hired labor; corresponding figures for a farmer-owner would be 3s. 8d. and 2s. 5d. respectively.

Statement A shows that in these "Inclusive" Costs, purely field operations—i.e., preparation of the land, seeding and harvest operations—are represented by 63.2 per cent. only of the expenditure, namely, £2 19s. 10d. per acre, or 3s. per bushel. The Balance—£1 14s. 10d. per acre, or 1s. 10d. per bushel—is absorbed by general expenses, interest on Capital, and Rent.

Statement B, on the other hand, shows the value of Hired Labor both directly or indirectly concerned in the growing of Wheat to have been 23s. 8d. per acre, or 1s. 3d. per bushel, or, again, 25 per cent. of the inclusive costs. From the standpoint of a farmer and family wholly responsible for management and manual operations, a charge of 1s. 3d. per bushel for Labor, would imply, with Wheat at 4s. 10d., that the farmer and family would be receiving payment for their Labor from a 19.46bush. harvest at the rate of 23s. 8d. for every acre harvested, or at 1s. 3d. for every bushel reaped.

Let us assume, by way of a concrete example, that a Farmer and Family reaped 19.46 bush. per acre from 300 acres of Wheat; on the Turretfield basis inclusive costs would have been represented by £1,420. If we assume, further, that the Wheat realised on sale £1,420, i.e., costs of production on the farm, although the year's transactions would have ended without any Net Profits, the farmer and family would have earned for their Labor £355, plus £346 representing interest on Capital. These assumptions imply, however, that the Wheat should have sold at 4s. 10d. per Bushel on the farm: but with Wheat at 2s. no interest could be paid on Capital engaged; no provision could be made for depreciation on improvements and plant; no payment would be received for a year's toil; the 2s. would, in fact, do no more than meet the costs of the purchase of essential material, rates and taxes, and other incidental expenditure.

Such, therefore, would be the unenviable position of the farmer working a Wheat Farm under Turretfield conditions in the current season; and it is to be feared that the plight of the man working on cheaper and more easily worked land is not much better because of normally lower yields.

Turretfield mean Costs of Production have been given as £4 14s. 8d. per acre for a 19.46bush. harvest; if we reduce these charges to £3 an acre, the cost per Bushel would still be 5s. for a 12bush. average; and even if we deduct 15s. for labor costs, £2 5s. would represent 3s. 9d. a bushel, a figure close on double the price at present offering for Wheat.

In Statement B, Labor (direct and indirect) is given as £1 3s. 8d. per acre; this figure includes, in addition to ordinary field labor (direct), a certain amount of Labor included in values given elsewhere for use of Horses and Implements (indirect labor). Details concerning mean direct and indirect labor for the 1922-30 period are shown below:—

|                                                                                               | Per Acre. | Per Bushel. | Percentage of<br>Mean Inclusive<br>Costs. |
|-----------------------------------------------------------------------------------------------|-----------|-------------|-------------------------------------------|
|                                                                                               | s. d.     | s. d.       | %                                         |
| Direct Field labor .....                                                                      | 18 2      | 0 11.2      | 19.2                                      |
| Indirect labor (use of horses) .....                                                          | 3 10      | 0 2.4       | 4.0                                       |
| Indirect labor (use of implements) .....                                                      | 1 8       | 0 1.0       | 1.8                                       |
| Total mean value of labor, direct and<br>indirect, concerned in the growing of<br>wheat ..... | 23 8      | 1 2.6       | 25.0                                      |

The mean rate of payment of Labor at Turretfield has been at the rate of 1s. 4.23d. per hour, and it is therefore possible to determine the number of hours of work involved in Wheat growing from costs recorded in the various accounts. These have been summarised in the statement below:—

*Summarising number of Working Hours per Acre involved in Wheat  
Growing (1922-30 Means).*

|                             | Costs. | Corresponding<br>Hours. |
|-----------------------------|--------|-------------------------|
|                             | s. d.  | Hours.                  |
| Direct labor—               |        |                         |
| Tillage of fallows .....    | 4 9    | 3.52                    |
| Seeding operations .....    | 2 8    | 1.98                    |
| Spring Tillage .....        | 0 1    | 0.06                    |
| Harvest Operations .....    | 3 10   | 2.85                    |
| General Expenses .....      | 6 10   | 5.02                    |
|                             | 18 2   | 13.43                   |
| Indirect Labor .....        | 5 6    | 4.07                    |
| Inclusive Labor Costs ..... | 23 8   | 17.5                    |

Thus, then, at Turretfield in the growing of Wheat on Bare Fallow  $17\frac{1}{2}$  hours labor per acre spread over 18 months have represented inclusive requirements over a period of eight successive seasons; and as the average working day on the farm has been  $9\frac{1}{2}$  hours, this represents 1.84 days per acre. Further, if we assume 307 to be the working days in a calendar year, one man could be responsible for 167 acres of Wheat under Turretfield conditions.

Finally, it remains to be stated that the expenses of the Wheat Grower do not end with the Harvesting of his grain. He has still to deliver it to market before accounts can be definitely closed. This additional item of expenditure will naturally vary with the distance of the farm from places of delivery, the condition of the roads, etc. According to circumstances, Wheat at Turretfield has been delivered to market by our own teams, or by the teams of contractors. Costs of delivery by our own teams of 7,354bush. over several seasons have been as follows:—

|                                         | Total. |       | Costs Involved. |     |
|-----------------------------------------|--------|-------|-----------------|-----|
|                                         | £      | s. d. | Per Bushel.     |     |
| Labor .....                             | 50     | 10 7  | 0               | 1-6 |
| Use of Horses .....                     | 47     | 11 4  | 0               | 1-6 |
| Use of Implements .....                 | 2      | 19 9  | 0               | 0-1 |
| Sundries .....                          | 0      | 12 7  | —               | —   |
| Cost of conveying Wheat to Market ..... | 101    | 14 3  | 0               | 3-3 |

In 1927-28 Wheat was delivered by contract at 2.24d. per Bushel (5,624bush); in 1928-29 at 1.93d. (5,567bush); and in 1929-30 at 1.5d. per bushel (7,554bush). If we average out costs incurred by the farm in earlier years and contract costs of the past three years, we get a mean rate of 2.26d. per Bushel representing costs of conveying Wheat from the farm to usual places of delivery.

Hence, the mean inclusive cost of growing and delivering to market a 19.46bush. harvest of Wheat has been represented at Turretfield by 5s. 0½d. per bushel.

#### B. WHEAT SOWN ON PEA STUBBLES.

During the past four seasons small areas of pea stubble land—34.9, 34.5, 44.08, and 19.42 acres respectively—have been sown to Wheat and subsequently harvested for grain. Expenditure connected herewith has been analysed in Table XIV.

Crystal Brook and Port Pirie.

It should be observed that over a period of four years—1926-30—the mean yield per acre of Wheat grown on Pea Stubbles has been 15.94bush., against 19.2bush. for Wheat grown on Bare Fallow over the same four-year period.

I have summarised below in Table XV. mean expenditure incurred in growing Wheat on Pea Stubbles—1926-30—in comparison with corresponding Mean Expenditure for Wheat grown on Bare Fallow—1922-30.

TABLE XV.—*Contrasting Mean Expenditure incurred for Wheat after Pease with corresponding expenditure for Wheat after Bare Fallow.*

|                                              | Mean Cost of Wheat Grown on<br>Pea Stubbles.<br>(1926-30). |           |             | Mean Cost of Wheat Grown on<br>Bare Fallow.<br>(1922-30). |           |             |

Mean yields per acre .....

15.94bush.

19.46bush.

It should be observed that whilst in Table XV. the costs of Wheat sown on Bare Fallow represent the means of eight successive seasons—1922-30—those of Wheat following Pease are the means of four seasons only—1926-30; and that in consequence the latter are perhaps less representative of local conditions than the former. If, however, we overlook this fact, the data show that wheat after Bare Fallow is more costly than Wheat after Pease, namely, 67s. 7d. per acre and 4s. 3d. per bushel, in the latter case, against 94s. 8d. per acre and 4s. 10d. per Bushel in the former. On these figures, Wheat at 4s. 6d. a Bushel would leave a margin of profit if following Pease, but a loss if succeeding Bare Fallow.

The two main items upon which economies are realised are Preparation of the Land and Rent, which aggregate 16s. 1d. per acre, or 1s. a bushel only, for Wheat after Pease, but 35s. 9d. per acre, or 1s. 10d. per Bushel for Wheat sown on Bare Fallow. The whole value of the practice, however, is contingent on a net profit being realised from the preceding Pea Crop; this is a question which will be discussed in another section of the Report.

Finally, we shall consider the number of Working Hours involved in growing Wheat after Pease in contrast with corresponding figures for Wheat after Bare Fallows:—

TABLE XVI.—*Summarising number of Working Hours per Acre involved in Growing Wheat after Pease in contrast with corresponding figures for Wheat after Bare Fallow.*

|                       | 13 8                        |    | 10-12         |        | 18 2                              |    | 13-43         |        |
| Indirect Labor .....  | —                           | 3  | 10            | —      | —                                 | 5  | 6             | —      |
|                       | 3 10                        |    | 2-82          |        | 5 6                               |    | 4-07          |        |
| Inclusive Labor Costs | —                           | 17 | 6             | —      | —                                 | 23 | 8             | —      |
|                       | 17 6                        |    | 12-04         |        | 23 8                              |    | 17-5          |        |

Thus, then, whereas Wheat following Bare Fallow absorbs 17½ hours per acre of Labor, the corresponding figure for Wheat after Pease would be 13 hours only. Reducing these figures to 9½ hour-days, these figures would become 184 days for 100 acres of Wheat sown on Bare Fallow, against 136 days for a corresponding area sown on Pea Stubbles. The comparison cannot be pushed further because obviously Labor absorbed by the Pea Crop must also be taken into consideration, and this will be done when dealing with the Pea Crop.

(To be continued.)

## SOME PROBLEMS AFFECTING DAIRY FARMING IN SOUTH AUSTRALIA.

[Paper read by Mr. H. B. Barlow, H.D.A., Chief Dairy Instructor, at the Forty-first Annual Congress of the Agricultural Bureau.]

The problems I particularly desire to draw attention to may be divided into two groups:—

- (a) Those affecting production.
- (b) Those affecting manufacture.

Although it may appear to some people that manufacturing has nothing to do with the farmer, this is quite a mistaken impression, since the manufacturer absolutely depends on the quality of the raw product to enable him to make a sound article.

The problems affecting production might be divided as follows:—

- (a) Suitable cattle.
- (b) Economical feeding.

With the knowledge available throughout the world of the productivity of individual cows, it must be accepted that obtaining the right sort of animal is of the utmost importance to successful dairying. What is the best means of obtaining this animal?

Experience shows that it is practically impossible to buy a really good dairy herd, unless under exceptional circumstances and by paying exorbitant prices, and this method can be considered as beyond the means of the average dairyman.

This statement is particularly true at the present time, and is accentuated by the fact that there has developed throughout the last 18 months at least, a strong tendency on the part of the landholders generally, to make dairying a much more important part of their farming operations. The reasons for this decision are not hard to understand.

Both wheat and wool have shown a strong tendency to decline in value, and at the same time, until just lately at least, the value of dairy products has remained at a satisfactory level.

Additionally, farmers generally have been forced into the position of appreciating the value of an income, no matter how small, which could be depended upon as being available each fortnight.

Economically, this is one of the strongest factors in favor of dairying.

Whatever the reason, South Australia at the present time is very short in dairy cows at a profitable age, and at times such as these this is a very serious matter, inasmuch as the demand will tend to force the price of stock too high for profitable working, thus bringing about much the same economic position as has occurred when prices paid for land were too high.

### BREEDING YOUNG STOCK.

The question of making up this shortage in dairy cows is economically very important, and, in my opinion, the only sound and economical method of building up depleted herds is by breeding and rearing young stock. It may possibly be suggested that the breeding of young dairy stock is not a paying proposition from the individual's standpoint, although it would be of advantage to the State generally. To a great extent this viewpoint has been developed, firstly by the opening up of larger milk areas in our Hills districts and the Adelaide Plains, and thereby diminishing the amount of skim milk available for rearing calves; and, secondly, owing to the phenomenally high prices which have been ruling for vealers during the last few years.

The fact that relatively high prices have been procurable for calves six weeks to two months old has been the reason for a very serious drain on our dairy herds.

Admittedly the dry seasons experienced in the Lower and Middle North, coupled with the scarcity of feed, have made the acceptance of this avenue for obtaining a small amount of ready cash very attractive, but the cumulative effect has put us in a more or less serious position. Notwithstanding these facts, I still contend that the breeding and rearing of our own young stock is the only possible way to establish and maintain sound and profitable dairy herds, and the larger the herd the more important does this matter become.

Granted that this policy is acceptable, it is imperative that only a pure-bred bull developed from high producing ancestors should be used if a sure and economical method of improving the production of the herd is required.

In this connection the Government is assisting very generously by subsidising approved bulls, and the progeny of these subsidised bulls are shown—and will continue to show—a marked improvement on the production figures of the State generally.

#### FEEDING.

Since the modern dairy cow is only an animate machine, developed by man, in order that large quantities of crude foodstuffs (pastures, &c.) should be turned into milk for the manufacture of dairy products, the feeding question is of tantamount importance.

Every ounce of milk a cow produces must and can only be procured from the food which the cow consumes, therefore, if a regular supply of milk is required, a regular supply of food must be available.

So far as this State is concerned, excepting perhaps on the irrigation areas of the River Murray, and even there perhaps with advantage, it must be an accepted policy that, at least for a few months each year, dairy cows must have a certain amount of hand feeding if satisfactory returns are to be expected.

This necessity immediately opens up the question as to ways and means.

It is an acknowledged fact that, except in extreme cases, if dairy cows are to be fed economically the feed must be produced on the farm, and the ration the cows are fed must be controlled by the crops which can be grown or stored.

Throughout our Hills and South-East districts, where heavy crops of clover or meadow hay can be grown and cured, the obtaining of the bulk ration is fairly simple. In these same districts this bulk ration can be supplemented with advantage by grain, in the shape of oats, barley, and peas. These grains fed in a crushed form either singly or together, will be found of great assistance when natural pasture is scarce.

Pastures in these areas can also be supplemented by having a small lucerne patch for summer feed, or planting such summer growing crops as Sudan grass or maize, and in the damp gullies cow grass and strawberry clover. Improving pastures by establishing rye grass and *Phalaris tuberosa* (*bulbosa*) also holds out great possibilities.

In the lower rainfall areas we must, to a much greater extent, depend upon cereal crops (wheat, oats, &c.) as our main stays.

Generally speaking, the winter and spring months can be expected to give fairly satisfactory, and in many cases excellent, pasture conditions which can be very often improved by the judicious use of superphosphates as a top dressing; but, generally speaking, the summer feeding becomes a problem.

The establishment of lucerne is of great assistance, and should, I think, be developed as much as possible. If any means of watering is available, so much the better.

Although cereal hay or chaff is not absolutely ideal for dairy cattle, supplemented by green feed when available, crushed grain, and, if possible, a little bran; and in cases, especially during very dry spells, the judicious use of molasses, excellent returns can be obtained.

#### ENSILAGE.

One avenue of storing food has been greatly neglected, and that is ensilage. As a food for dairy cattle during the dry weather, ensilage has few equals and can be made from practically all cereals or natural herbage, &c., either in a tub, pit, or stack.

In dry districts a pit dug in the side of a hill can be expected to give excellent results, and large circular silage stacks will also be quite satisfactory and have a comparatively small percentage of waste. In small stacks the percentage of waste is comparatively high. It is worthy of note that, excepting irrigation areas, most of the highest yielding herds, practically throughout Australia, are fed for the greater part of the year with ensilage as their main bulk ration. A well-filled pit or well-made stack of ensilage will keep in excellent order for years, practically no deterioration taking place.

#### PROBLEMS OF MANUFACTURE.

The greatest problem the dairy farmer in South Australia has to contend with is getting his product—chiefly cream—to the manufacturer in a sound condition.

Our knowledge of butter manufacture has increased greatly during the last few years. The most efficient machinery, churns, pasteurisers, coolers, cream vats, &c., have been developed, but the quality of the original cream is still the controlling factor of butter quality.

Although present-day methods of treatment can be expected—in fact, do, prevent rapid deterioration after treatment—still we are unable to so rejuvenate or alter the quality that a good butter can be manufactured from an inferior cream.

There are many factors which tend to cause cream to depreciate in quality, but depreciation is generally caused by bacterial action and the length of time the cream is held before reaching the manufacturer. Both these factors are accentuated by the climatic conditions.

The average quality of cream, when it reaches the factory in South Australia, is not nearly so good as we would like to see, except possibly for a few weeks in the early part of the season.

#### CLEANLINESS.

The methods to be adopted—to at any rate lessen the depreciation through bacterial action—are well known, and generally quite simple of application and dependent solely on the practice of a sound system of hygiene throughout all processes. Since much the greatest amount of bacterial infection can be traced to contamination from utensils, careful attention to the washing of these will generally have an immediate effect in the direction of improved quality. Too great a stress cannot be placed on the absolute necessity for carefully washing all dairy utensils immediately after use, and having washed them, a liberal use of boiling water for scalding purposes will lay the foundation for a choice article. Provided all dairymen will give this matter the serious consideration it deserves, and carry out the job thoroughly, we will find that a rapid improvement in quality will take place. The obtaining of this very necessary improvement is easy of attainment, with practically no added expense and very little, if any, added labor.

#### HOLDING THE CREAM.

The second main cause of inferior cream, that of age, is not nearly so easy to overcome. Even cream procured under ideal conditions deteriorates rapidly with age, and this deterioration is accentuated or hastened in hot weather. The cream becomes first stale, and then develops a tallowy flavor. Any cream which is more than three days old in summer time can be expected to be falling off in quality, and even during the winter months the chemical changes which take place make four or five days old cream a doubtful proposition.

Notwithstanding our vaunted improvements in methods of manufacture, we are still unable to improve cream once it has developed a stale or tallowy flavor. As a matter of fact, since these flavors are due to chemical changes taking place, pasteurisation, which

has wrongly been quoted as a cure for all evils, has a tendency rather to accentuate than lessen the trouble. This underlying stale flavor is the main trouble with the majority of our inferior butters.

Provided the amount of cream available is sufficient to warrant the cream being forwarded to the factory more often than three or four times a week in summer and at least twice a week in winter, this trouble can be easily rectified.

Unhappily, we have to depend for the great bulk of our cream from people who only keep a small number of cows, and may live long distances away, with the result that the cost of transport very often does not warrant quick and regular deliveries of the cream to the factory. In these cases, the problem is very hard to solve satisfactorily, but by keeping the cream as cool as possible, stirring two or three times each day, mixing the fresh cream as soon as it is cool with the old cream, and keeping it as cool as possible during transport, much can be done.

The manufacturers can be depended on to make the best possible use of the cream, and the larger the amount of comparatively fresh cream which is available, the greater the amount of slightly inferior cream can be used.

Although this suggestion may appear like "robbing Peter to pay Paul," nevertheless the blending of choice and slightly inferior cream must be recognised as an accepted commercial and economic practice, as our object is to obtain the greatest good for the majority, but, at the same time, we must uphold the quality of our finished product and give the consumer a sound article.

So serious has this matter become that it will be absolutely essential for us to enforce the efficient grading of all cream by the factory representatives, and although the fact of the cream being classified as second grade will no doubt come as a shock, and possibly cause a considerable amount of heartburn amongst producers, nevertheless, it is the only way to bring about a definite improvement in cream and butter quality.

Admittedly strict grading of cream might seem to adversely affect those persons who have to send their cream long distances, yet it is doubtful whether, in the long run, it will materially affect their net returns, and extra attention given to the details of handling, &c., can confidently be expected to show a marked improvement, and may even considerably lengthen the accepted time during which the cream will remain sound.

I do not profess to have touched on all our problems, but I have picked out those which appear to me to be of paramount importance at the present moment, with a hope that some discussion might accrue, and thus help to solve—if only in part—some of the problems with which we are confronted.

## THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

## FORTY-FIRST ANNUAL CONGRESS.

[Continued from page 368, *Journal of Agriculture*, November, 1930.]

## TUESDAY, SEPTEMBER 16TH.

Portion of the papers read at the Men's Congress on Tuesday, September 16th, appear elsewhere in this issue.

At the Horticultural session held in the afternoon, the following resolution was carried:—"That results of investigations into the cause of and remedy for gumosis in apricots be made available at the Conference of Non-Irrigated Fruit Areas, at Angaston, in November."

## WOMEN'S BRANCHES.

Delegates from Women's Branches met in the committee room of the Way Hall on Tuesday morning, September 16th. Mrs. J. Hammatt (Williamstown) presided and Mrs. E. L. Orchard acted as Secretary.

## THE COMMON-SENSE KITCHEN.

Mrs. H. BILLING (Wilkawatt) read the following paper:—

In an article entitled "How Can I Make My Kitchen Better?" the opening paragraph read something like this: "If yours is like 99 out of 100 kitchens it is in bad need of bettering. This, the most important room in the house, especially to the woman who does her own work, is usually the worst contrived. It generally lacks proper light and ventilation, and being at the back of the house, rarely has a pleasant outlook. The best room is probably towards the view and too often closed and unused, while the farmer's wife spends most of her waking hours in a kitchen backed towards the barns, or washing dishes against a dead wall. She is apt, too, to keep her cooking utensils, from heavy iron pots inherited from her grandmother down to the eggbeater and nutmeg-grater, in one cupboard and her dishes in another—maybe the length of the long kitchen apart. Does this description fit you?"

Another writer puts it this way: "There are kitchens *and* kitchens. Some of them are a blot on the escutcheon of the housewife and shriek aloud the reason for her weariness."

We do not often realise that the little unnoticed strains are a greater wear and tear on one's vitality than are the big ones.

The kitchen is the central point of the housewife's energies, and if forethought is used in the kitchen outfit there will be a direct return in health and comfort to all those who dwell under the roof.

"Conservation of energy, effort, and of time are essential to the modern woman who has no desire to spend half her life cooking and washing up and grubbing round generally. She wants a few hours to herself and enough vitality left over from housework for recreation and the refreshment of her mind which is not necessarily like a vegetable because she deals with vegetables for part of each day of her life."

There are just two rules for constructing an ideal kitchen—

*First*—Make sure that everything you need is ready to hand; that is, make it convenient; eliminate all unnecessary fetching and carrying.

*Second*—Make it pretty: in other words, make it good to look upon and therefore restful to work in. Make it productive of good and healthful cookery by means of right tools and utensils adapted to their work.

*Good Service Tests*—

1. Each tool or utensil must do some one thing so efficiently that its presence is warranted.
2. Or: it must be adaptable to many purposes.
3. Must require only a fair amount of time and care to keep it in order.
4. Must be sufficiently durable to return a reasonable service for the purchase price, weight and durability must be considered.

*Types of Kitchen*—

1. Kitchen: living room of family as well as the workshop of the home.
  2. Maid's sitting room when day's work is done.
  3. Solely the workshop of the woman who runs her house without any domestic help.
- A southern aspect is best in this country; the kitchen must be bright, airy, and roomy.

*Flooring*—

Flags, tiles, bricks, concrete or wooden boards (boards covered with inlaid linoleum are best).

*Walls*—

1. Glazed tiles or painted walls are ideal.
2. High-tiled dado with distemper or other suitable finish, above.
3. Whole wall washed with simple distemper.
4. Varnished paper also appropriate.
5. White-washed walls.

Avoid shadows at table and stove; use wall lights rather than lights suspended from ceiling; have a window in the chimney.

A small kitchen saves much walking about, but it is more difficult to work in, as constant tidying up is necessary. The smaller the kitchen the more thought is needed in its equipment.

Plan for the kitchen to be within easy reach of the dining-room. Compactness is a great advantage in any kitchen, and the disposition of cupboards, sink, stove, and table should be thought out with a view to minimise the number of steps that will have to be taken in the various duties to be performed. Try this: place the sink or washing-up table under the window, with stove on the right and kitchen cabinet on left. The sink should be at such a height that the arms of the worker can be stretched out in a normal working position without bending the back at the waist or shoulders. The working surface for the table could be a slab of glass, or marble or linoleum covered. Use newspapers to save work. It is a great save to have an extra table covered with heavy tin or zinc; if without one, keep a few pieces of wood 4 to 5 inches square, 1 inch thick, with a

## PARAFIELD POULTRY STATION.

NOW BOOKING ORDERS FOR SPRING, 1931.

### Eggs for Hatching and Day-old Chickens.

WHITE LEGHORNS ONLY. DELIVERY—JULY, AUGUST, and SEPTEMBER.

#### PRICES—

EGGS—10s. per Setting of 15 Eggs; Incubator Lots, £2 10s. per 100.

DAY-OLD CHICKENS—17s. 6d. per dozen, £6 per 100. Free on rail, Salisbury.

Further particulars can be obtained from the Manager, Parafield Poultry Station, Salisbury.

C. F. ANDERSON, Manager.

screws in the end of each one, hang on a nail or hook, over the worktable; these are useful to stand saucepans on, convenient to cut meat on, to slice bread, roll lemons, and for many other purposes. The sink must have a syphon trap to prevent return of foul gas into the house, with a gully trap outside the wall.

Have nothing on the floor—the bare floor is more easy to sweep and mop. Use shelves—not too wide, as wide shelves are conducive to waste, muddle, and dirt. Paint, enamel or lacquer surface, or cover with linoleum or oilcloth. Imagine a background of blue, green, cream, or pale grey.

If cooking utensils and saucepans are hung or neatly ranged on shelves there is no losing a saucepan lid, no grovelling on the floor groping for a dish that has slipped right to the back of the wide shelf.

Cover cookery books with greaseproof paper.

Divide a cutlery drawer into compartments; have it near at hand for washing up. Place platerack above sink. Keep groceries in glass jars—wide-mouthed, as in sweet shops.

Have a towelrack or line and a roller towel, a good clock, a traymobile, a kitchen slate or book with pencil attached, a scrapbook for hints and recipes, and a small armless rocker and a stool.

After breakfast each day take a 10 to 15 minutes rest and read, with everyone started off to school or the day's activities; the rest will give you a chance to collect your thoughts, and the few minutes spent in reading will refresh your mind and give your spirit a lift through the dish-washing.

---

#### FLOOR POLISHING.

Mrs. McCall (Kalangadoo) contributed the following paper:—

Floor polishing, as we all know, is rather a long and tiresome task, but in the following way I think I have cut it down to a minimum of labor and expense with a home-made varnish.

Not only is this varnish suitable for stained boards and linoleums, which it preserves and lengthens their life, but is equally successful when used for varnishing skirting boards, doors, all paintwork, will double the life of fly-wire, will renovate and make travelling bags and suitcases like new, will make waterproof school attache cases—in fact its uses are too numerous to mention. For general use, dissolve 4ozs. brown shellac in 1 pint methylated spirits. For kitchen floors and stained boards that require a hard surface:—4ozs. brown shellac, 2ozs. resin in 1 pint methylated spirits.

As the varnish has a slight tendency to darken, I have found it advisable to add 2ozs. white shellac to the general-use recipe for very light-colored linoleums. By shaking the mixture daily it will take about four days to dissolve, and will keep perfectly if airtight, otherwise the spirit will evaporate. Have surface of floors clean and dry, and working away from the light apply with a light, even stroke of the brush till the whole floor has been done. I find it advisable to give the floors three coats three times during the first year; afterwards once every six to nine months will be ample. On a bright, sunny day I am able to scrub and give three coats of polish to a room 18ft. x 14ft., linoleum and boards, and the cost did not far exceed 2s. 6d.

The greatest advantage of this varnish, which gives a brilliant, mirror-like surface, is that it is not slippery—not even to a child. To clean, mop briskly every other day with an oiled mop, and should a mud stain prove obstinate remove with a damp cloth. Kitchen floors—wash in lukewarm water.

Miss Lois Allen, B.A. (Education Department) addressed delegates on the subject, "Differences in Temperament and Ability in Children."

(To be continued.)

## TOMATO DISEASES IN SOUTH AUSTRALIA AND HOW TO CONTROL THEM

with special reference to Glasshouse Tomato Culture.

[By GEOFFREY SAMUEL, M.Sc., Plant Pathologist, Waite Agricultural  
Research Institute, University of Adelaide.]

[Continued from page 377, *Journal of Agriculture*, November, 1930.]

### OTHER ROOT-ROT DISEASES—continued.

*Fusarium Wilt* (caused by the fungus *Fusarium lycopersici*).—In some countries *Fusarium* wilt is one of the worst and most troublesome root-rot diseases of the tomato. Although many plants from glasshouses round Adelaide have been examined, no definite case of *Fusarium* wilt has yet been found. *Fusariums* fairly closely related to *Fusarium lycopersici* have frequently been obtained from rotting roots, but in no case have they exactly resembled this fungus, either themselves or in their effects on the plant. It is rather difficult to understand why this fungus is not known near Adelaide, for it is stated to be of considerable importance in Queensland and New South Wales, and to a less extent in Victoria. It may be that in South Australia by the time the soil conditions become warm enough for the disease to be bad, the plants are fully grown, or it is possible that the South Australian Early Dwarf Red, which is the variety almost exclusively grown in glasshouses, here possesses some resistance to the disease. (The best method of control in areas where the disease is present is the growing of resistant varieties, e.g., Norton, Marvel, Columbia).

The symptoms of *Fusarium Wilt* are rotting of the roots, browning of the wood inside the roots and stem, and sickness and yellowishness of the top of the plant with or without wilting. This disease is one which is severe under high temperature conditions, in contrast to *Verticillium Wilt*, which is a low temperature disease.

*Pythium Root-rots*.—On a number of occasions isolations from diseased tomato roots have yielded several species of *Pythium* fungus. Further research work will be needed before the importance of these can be properly judged. Under certain soil conditions, especially where the subsoil is too close to the surface for the best growth of tomatoes, they appear to play an important part in root-rotting. Roots die back from the tips, the tops of the plants wilt in the warm part of the day, and growth cannot proceed vigorously.

*Control of Root-rot Fungi*.—As explained in the discussion on *Verticillium Wilt*, steam sterilisation would be the best way of ridding soils from these root-rot diseases. Since heat is not necessary in the growing of the tomatoes here, however, no growers have any apparatus for steam sterilisation. As land gets more expensive it is probable that co-operative steaming plants may be established, but for the present growers find it cheaper simply to move their houses to a fresh piece of ground which has had a spell for several years. The glasshouses are usually spaced at equal glasshouse widths, so that all that is necessary is to move the roofs across. It is possible, however, that larger glasshouses and taller varieties may later come into favor, and these would not be so easily shifted.

Apart from this, the best advice that can be given is to see that the growing conditions for the plants are as good as possible. The old roots of the previous crop should, of course, be carefully pulled out and burnt.

The suggestion given before to allow the soil to dry out thoroughly once or twice in the greatest heat of midsummer, when the plants are out of the houses, might also be tried here. If these methods, coupled with the best conditions of growth and manurial treatment, do not overcome the trouble, the only solutions left under our present conditions are either the moving of the glasshouses or trying dwarf beans to give the soil a spell from tomatoes for a year. This was not recommended for *Verticillium* Wilt, because beans have been found to be affected by the latter disease.

#### LEAF-SPOT.

*Description.*—Leaf-spot is easily recognised as small circular or irregular-shaped dead spots on the leaflets (Fig. 21). The spots are usually brown, paling to light brown or ashy color in the centre, and frequently the green tissue round the spots becomes yellowish; a careful examination will reveal minute black specks present at the centre of the spots.

FIG. 21.—Tomato leaflets showing the dead spots with light brown to ashy-colored centres—due to the Leaf Spot fungus.

In glasshouses leaf-spot is usually only bad where there is some drip on to the plants. It is frequently worse on tomatoes in suburban gardens, especially when they are watered overhead every day or so and are not pruned and straggle over the ground. Under these conditions, where the lower leaves especially are under constantly moist conditions, leaf-spot can sometimes become very bad and the leaves be riddled with spots. Badly diseased leaves turn yellow and die, and the disease gradually spreads upwards, seriously defoliating and injuring the plant.

*Cause.*—Leaf-spot is caused by a fungus (*Septoria lycopersici*). The small black specks in the centre of the leaf spots are the spore-sacs of the fungus, and each one can contain some hundreds of the fungus spores (Fig. 22.). The spores of this particular fungus are thin, elongated, and colorless,

but so small as to be invisible to the naked eye. They are extruded through the mouths of the spore-sacs under moist conditions and lie in heaps of some hundreds in the centres of the leaf-spots. A drip of water or the splashing of overhead watering may then splash them on to other leaves, where they germinate under the moist conditions and fungus threads penetrate inside the leaf. The growth of the fungus inside the leaf causes the leaf tissue to die in the characteristic spot, and the fungus then forms its spore cases again in the dead tissue at the centre.

FIG. 22.—One of the small black specks, visible in the ashy-colored centre of a Leaf Spot, when magnified 250 times is seen to be a spore-case of the fungus producing some hundreds of long, thin, spores, which are pushed out through the neck, and can be splashed or washed about by overhead drip or watering.

*Control.*—In glasshouses the checking of drip or other conditions which keep the leaves moist should be sufficient to stop the disease. If difficulty is found in curing it this way the use of a copper-lime dust should prevent the trouble spreading.

In the open several precautions can be taken. If plants are pruned and staked they are rarely troubled with the disease under the dry climatic conditions here. Unpruned plants should be watered by trenches instead of overhead watering if the disease is seen on them. Straw placed under the branches so that they do not lie directly on the moist soil will aid somewhat. If the disease is actually spreading and causing trouble in spite of these precautions a Bordeaux Mixture spray will have to be applied. In countries with climatic conditions more favorable to the disease regular sprayings with Bordeaux Mixture are carried out. A copper-lime dust should be satisfactory if used thoroughly. Finally, the proper destruction of diseased leaves at the end of the season and growing the following year's crop on some other piece of ground will also aid in minimising trouble from this disease.

## EARLY BLIGHT LEAF DISEASE.

*Description.*—This disease is recognisable by the dark-colored, often concentrically-zoned, spreading spots on the leaves (Fig. 23). Very frequently the spots start from the margins of the leaves, which become curled round or twisted over somewhat. Affected leaflets finally dry and shrivel to a brown color. If not checked early the disease can cause considerable dying of the leaves and seriously reduce the vigor of the plants.

In America the stems and the fruit may also be spotted and the name nailhead-spot is often given to this form of injury. So far, however, it is only the leaves of the South Australian Early Dwarf Red tomato which have been found affected.

FIG. 23.—Tomato leaflets showing the dark-colored "zoned" spots of Early Blight. (See also Fig. 2.)

*Cause.*—Early blight is caused by a fungus (*Macrosporium solani*) which has been described on pages 256-7 (October issue).

*Control.*—This is a much more serious fungus in glasshouses than the leaf-spot fungus, for it seems to be able to attack the plant when much less moisture is present. No actual drip is necessary to enable it to spread, and the small amount of moisture which condenses on the leaves in the very early morning, provided it lasts long enough, is quite sufficient to enable the fungus to infect. In the cases which have come under notice it has been glasshouses some distance from the sea which have been most affected, and it seems probable that the greater fall of temperature at night, with deposition of a film of moisture on the leaves, has been responsible.

Any practices which tend to reduce the humidity should, therefore, be of some aid in controlling Early Blight. So far the disease has not been found in the large type of glasshouse, possibly because of the lower

humidity. Better control of ventilation in the smaller houses should be of assistance in keeping down the humidity at critical times, but it is unlikely that sufficient control could be obtained in this way alone to check the disease.

The picking off of infected leaflets during "inspections" of the glass-houses can do quite an appreciable amount of good in the early stages, before there are too many to deal with. It should really be done in the earliest stages of the spots, before the crops of spores have ripened, however, and a practised eye is therefore needed to detect the spots quickly.

FIG. 24.—Tomato leaflets shrivelling to a light-brown color due to the attack of *Pleospora* fungus. Usually numerous tufts of a blackish mould fungus appear on the dead leaves, but this mould is not the cause of the disease, and only establishes itself on the dead tissue under the humid conditions in the glasshouse. The affected leaflets finally die back to the leaf-stalk.

As soon as Early Blight spots are noticed a dusting with copper-lime dust should be given. Dusting with a sulphur dust should be of benefit if a copper dust is not available, but American experiments have shown that copper dusts are more effective against Early Blight than are sulphur dusts. Keep new growth covered with a film of dust by dusting every ten days or a fortnight.

Once again particular attention should be paid to the destruction of diseased material in the clean-up at the end of the season. It would also be advisable to give a good lime-sulphur spray inside the houses which were infected, directing the spray into all cracks of the woodwork.

Finally, potatoes should not be grown near the houses, for they are subject to the same disease.

#### PLEOSPORA LEAF BLIGHT AND FRUIT SPOT.

*Description.*—This is a disease which requires further scientific examination before much can be said about it. A case occurred in which a great deal of damage was being done to the leaves of tomato plants in one house,

and the trouble subsequently spread to four other houses. The leaflets got dead patches on them, of a pale chamois-leather color, which quickly spread until the whole leaflet was killed (Fig. 24). Tufts of greenish-black mould soon appeared on the affected leaflets, but these were only secondary, establishing themselves as saprophytes on the dead tissue in the humid conditions. Affected leaflets quickly died back to the stalk, and it was usually not long before all leaflets on a leaf were affected. The disease gradually worked up the plant, so that in bad cases the whole of the leaves, except those near the top of the plant were dead. Occasionally small spots appeared on the fruit (Fig. 25), but these were not very frequent.

FIG. 25.—Fruit-spots caused by the *Pleospora* fungus.

*Cause.*—An examination showed that there was a certain amount of Early Blight present in the houses, but on most of the dying leaflets no trace of Early Blight could be found. Early Blight spot is dark at the centre, and can scarcely be mistaken when known. Further examination was made by making isolations from the diseased spots in culture dishes. In by far the largest number of cases a fungus was obtained which first formed *Stemphylium* spores and later *Pleospora*.

*Stemphylium* spores were also noted on the affected leaflets in the glass-houses, and were at first thought to be the spores of a saprophytic fungus in the same class as the *Cladosporium*, which was the most abundant saprophyte.

The results were similar in isolations from the fruit spots. When the fruit was gathered, the spots were thought to be probably the “nailhead-spot” stage of Early Blight. In no case, however, was the Early Blight fungus isolated from these spots, but in every case the *Stemphylium-Pleospora* fungus. The Early Blight fungus was only obtained in culture from leaflets which showed one of the characteristic dark spots.

All the evidence from microscope and culture work, therefore, points to the *Stemphylium-Pleospora* fungus as being the one responsible for this definite type of leaflet death. Unfortunately the matter could not be followed up at the time as far as the final proof of parasitism of the fungus by inoculation experiments.

**Control.**—The fungus forms numerous spores on the surface of the dead leaflets, and these are readily blown about in currents of air and can evidently germinate with very little moisture present. Since the fungus is similar in its action to Early Blight, similar recommendations for control are all that can be given until we know more about the disease. The recommendations include early action with copper-lime dust if the fungus is seen, reduction of humidity as far as possible, and destruction of refuse and treatment of houses at the end of the season.

#### PHOMA FRUIT ROT.

**Description.**—This is typically a stem-end rot. A black, rotten patch is seen to start, usually at a crack in the fruit at the stalk end, and gradually spreads until half the fruit or more is rotten, with a charcoal black, crinkled skin.

**Cause.**—The disease is caused by a fungus (*Phoma destructiva*) which can only infect the fruit through cracks in the skin. Once it has gained entrance through a crack the fungus grows into the flesh of the fruit, causing the typical collapse and rotten patch. When it has grown for a certain time

FIG. 26.—(a) *Stemphylium* stage of *Pleospora* leaf blight fungus. Spore-bearing branches projecting from diseased leaf tissue and bearing spores. Magnified 250 times.

(b) A later stage of the same fungus, showing eight spores borne in an ascus sac.

it forms numerous black spore cases just under the skin of the fruit, so that the centre of the patch appears as if studded with very minute black pimples. Under moist conditions these exude small pinkish droplets, which are really little heaps of thousands of spores of the fungus.

**Control.**—The only case in which this fungus was found causing damage in South Australia was one in which another variety of tomato was being grown than the usual Early Dwarf Red. The fruit of this variety cracked at the stem end, whereas the Early Dwarf Red rarely cracks. The most important point in control would therefore appear to be to grow a variety in which the fruit does not crack.

As control measures to apply when the disease has appeared, the most important are:—(1) Pick affected fruit as soon as the patches are seen so as to prevent the production of large numbers of spores, and (2) spray the stem ends of the fruit with Bordeaux Mixture or dust with copperlime dust. This is not a certain preventive, however, since cracking of the fruit can lay open fresh unprotected tissues.

FIG. 27.—Black rotten patches starting from cracks at the stem end of tomato fruits, caused by the *Phoma* fruit rot fungus. Eventually half the fruit can become a coal-black rotten mass.

#### BLOSSOM END ROT.

*Description.*—Blossom end rot is very easily recognised from the large rotten patch which appears at the blossom end of the fruit (Fig. 28). It is usually roughly circular, but may at times be more irregular, or only on one side of the central point. The spot is usually rather soft in the early stages, becoming somewhat firm and shrunken when older, and

FIG. 28.—Tomato fruits showing the big rotten patch at the blossom end characteristic of Blossom End Rot.

changing from a putty color to a dark brown. In moist climates moulds often gain a footing on the dead tissue and complicate matters by starting a secondary rotting. This does not usually happen in the dry summer climate of South Australia, however, and the most familiar form of the trouble here is the round, firm, sunken, brown patch.

*Cause.*—The cause of blossom end rot is a period of drought for the plant just as the fruit is ripening. The plant need not actually droop from want of water, but the water-loss from the leaves may be more than the roots can supply and water be withdrawn from the fruits. At a critical period in the growth of the fruit, such loss of water results in the dead patch at the end of the fruit known as Blossom End Rot. The real cause is probably that as water is withdrawn from the fruit the acids present in the cell-sap become concentrated sufficiently to kill the cells. The exact mechanism of the process is not yet known, however, but it has been well established that no parasitic fungus is responsible for the condition, and that it is due merely to fluctuations in the water supply.

*Control.*—The obvious control measure, therefore, is to be sure that the plants do not suffer from lack of water at any stage. Tomatoes like a well-drained soil with plenty of water available. Something can be done to

FIG. 29. --Tomato fruits showing the tough white patch due to sunburn.

minimise the frequency of watering by hoeing and mulching (especially for the outdoor crop), but neither of these can relieve the tomato grower from the necessity for constant attention to watering.

#### WATERY FRUIT.

*Description.*—There is a condition of the fruit in which the flesh is not as firm as it should be, and does not ripen to an even opaque red color. The fruit has a slight watery appearance, so that parts of the network of veins become visible with semi-transparent areas in between. The "feel" of the fruit is slightly "bladdery," and not firm as it should be.

*Cause.*—The cause of this watery condition of the fruit has not yet been specially investigated, but it appears to result from the use of too much nitrogenous manure.

*Control.*—It must be remembered that stable manure, blood manure (or manure containing blood), sulphate of ammonia, and nitrate of soda all contain nitrogen. If more than one or two of these manures are being used the plant may be getting more nitrogen than it requires, unless phosphate and potash are liberally supplied also. If watery fruit is being

harvested, therefore, a dressing of one part of superphosphate and three part of sulphate of potash should be applied at the rate of about 50lbs. per 100ft. of house. Potash has an excellent effect in firming up soft fruit, and is needed by tomatoes in greater quantity than by most other plants.

FIG. 30. - A pallid leaf. The cause of this condition is not known, but increased manuring seems to benefit the plants.

#### PALLID LEAVES.

*Description.*—This is another trouble about which little is known yet. The leaves become “pallid” or whitish, especially in the central part of the leaflets, except that the normal green color often runs along the veins in parts (Fig. 30). It is quite distinct from mosaic in that there is no blistering or rolling of the leaves, and the mottling is not one of dark-green and lighter-green areas as in mosaic, but a general pallidity with veins of green going through it.

*Cause.*—The cause of this condition of the leaves is not known. In an experiment in which the sap from affected leaves was inoculated into healthy plants, no disease was produced in these plants. It is probable that the trouble is nutritional.

*Control.*—In one case where the trouble became particularly marked it was largely cured by the application of a dressing of manure containing a little extra sulphate of ammonia. Although nitrogen was possibly not the particular element which was lacking, the application of a dressing of manure may have effects in making other elements more available from the soil. The possibility of lack of iron or manganese being connected with the trouble should be investigated.

FIGS. 31 and 32.—Two forms of Rosette disease, the cause of which is not yet known.

#### BUCK PLANTS.

*Description.*—Occasionally big, rank plants with large stems and over-developed leaves, and without flowers or fruit, are found in glasshouses. They are usually called “buck” plants here, and are known as “bull plants” in America.

*Cause.*—The cause of this condition (gigantism) is probably some genetic abnormality, which is best expressed popularly by the word “freak.” Since the plants are of no use they are best removed as soon as they are noticed, for they are only using water and plant food which would be more profitably made use of by the normal plants alongside.

#### ROSETTE.

*Description.*—Rosette (often called “blue-top” in Victoria) is very easily recognised from the way in which the shoots “go blind” instead of developing normally. An excessive number of sideshoots are produced at the tips of the branches, but with small, undeveloped leaves so that the shoot is tufty in appearance (Fig. 32). The fruit bunches are stiff, with swollen and abnormal flowers which do not develop, or which develop only to small, tough, woody fruit. Sometimes the affected branches become very thick and swollen below the aborted flowers (Fig. 31).

Usually it is only odd scattered plants which become affected, but there have been occasional records of a single grower having some hundreds affected at the same time. The plants always start off normally, and do not develop the rosette habit until they are about a foot high.

*Cause.*—The cause of this disease is at present unknown. No parasitic organism has been found associated with it, and in two preliminary tests at the Waite Institute the sap of diseased plants failed to reproduce the disease when inoculated into healthy plants. Further research work will be necessary to determine the nature of the disease.

*Control.*—Since the cause is not known, little can be said about control. Fortunately the trouble is rarely sufficient in amount to call for definite control measures. A correspondent of the *New South Wales Agricultural Gazette* in 1904 stated that about half a patch of thirty plants growing under very dry conditions became infected, but that a few plants which obtained plenty of water developed normally. At all events, since affected plants are useless for further fruit-bearing, they are better pulled out.

(*To be continued.* The next article will deal with Insect Pests.)

## ORCHARD NOTES FOR SOUTHERN DISTRICTS, DECEMBER, 1930.

---

[By CHAS. H. BEAUMONT, District Horticultural Instructor.]

Picking and marketing of soft fruits will be the principal work for the month. It is not an easy proposition to carry this out satisfactorily, because the fruit ripens unequally, and to make a good pack, firm and ripe fruit should not be put together, but into separate containers. In any case the fruit must have started to ripen before it is picked, or it will not ripen at all, and the nearer the fruit is to fully ripe on the tree the better will be the flavor. Trays should be used for the best of soft fruits. Do not waste fruit which is too soft to pack, dry it. A pamphlet giving directions about treatment of fruit for drying may be obtained from the Department of Agriculture by sending a twopenny stamp for postage.

The comparative scarcity of apples will make the attack of codlin moth more noticeable this season, and every effort must be made to prevent too great a percentage of fruit from damage. Arsenate of Lead is the remedy, and a covering of this should be kept on the fruit always, unless it is intended to try the white oils later on.

Root borers will be found in pairs on the foliage now and may be picked off, or if a strong mixture of Arsenate of Lead is being used for curculio beetle it will also kill the borers. Borers in apricot, peach, and almond may be stopped by soaking a small bit of cotton wool in petrol and inserting in the hole; stop the hole with soil rubbed in. Aphides will need to be sprayed with Black Leaf 40 and soap, or parasites may be obtained by sending sixpence to the Blackwood Orchard to pay postage. Cutworms must be stopped with Arsenate of Lead. Use sulphur dusts for Oidium of the vine, and Bordeaux for downy mildew if it should start. Use Lime Sulphur or Sulphur Dust for red spider if it is observed. Cherry or pear slug can be stopped by the use of Arsenate of Lead, either wet or dry; many shrubs are attacked by this pest. Do not use sprays on ripening cherries.

Strawberries need water to grow to their best size, and mulching is helpful.

Almonds should be sized, and varieties kept separate if the best prices are expected.

Open up tomato houses for ventilation on hot days, and use only enough water to keep the soil moist—not wet; keep free from weeds outside as well as inside the house.

Rub off all unnecessary shoots from vines and trees.

Budding may be commenced; use only buds from proved trees.

## RED COMB EGG ASSOCIATION.

## OFFICIAL SINGLE TEST.

## EGG-LAYING COMPETITION, 1930-31.

Conducted at the Parafield Poultry Station under the Supervision of the Department of Agriculture.

Total No. of Pens.—Section 1. White Leghorns—204 birds; Black Minorcas—3 birds.  
Section 3. Black Orpingtons—30 birds. Section 4. Rhode Island Reds—6 birds.

Twelve Months Test. To start on April 1st, 1930.

Section 1.—White Leghorns, 1 to 204; Black Minorcas, 205 to 207.

## SULPHURING APRICOTS.

REVISED PROCEDURE RECOMMENDED BY COMMITTEE CONVENED TO DRAW UP A STANDARD METHOD.

Last year a committee, consisting of Messrs. Geo. Quinn (Chief Horticultural Officer, South Australia), C. G. Savage (Director of Fruit Culture, New South Wales), A. V. Lyon (Officer in Charge, Research Station, Merbein), and W. R. Jewell (Research Chemist, Department of Agriculture, Victoria), was convened by the Council for Scientific and Industrial Research to consider the question of sulphuring dried fruits, and it issued a recommended procedure which, in the case of apricots, might reasonably be expected to give a satisfactory product without an excess of sulphur dioxide. The sulphuring of peaches and pears, in the opinion of the committee, did not offer any serious difficulties.

As a result of experimental work conducted by the members of the committee last season it is now in a position to recommend a somewhat modified procedure which is likely to give more satisfactory results. This procedure is outlined below.

In view of the fact that quantities of apricots were again oversulphured last season, it would appear that some growers have still failed to realise the care that is essential in sulphuring, and it is apparent that growers must take more care if the resultant product is to comply with the regulations in force here and in England regarding the amount of sulphur dioxide permitted in dried fruit. In his own interests, therefore, every grower producing dried apricots is strongly recommended to adopt the procedure outlined below, when he should experience little difficulty in keeping the sulphur dioxide content below 14 grains per lb., and, at the same time, produce a marketable product.

### RECOMMENDED PROCEDURE.

(a) *Maturity*.—It is essential that all fruits be picked "eating ripe," and that, when cutting, all firm or overripe fruit should be put to one side and either discarded or sulphured separately, so that all the fruit in one chamber may be of uniform maturity, and, therefore, yield a uniformly sulphured product. It is recognised that firm fruit absorbs sulphur less readily than ripe, and generally gives an unsatisfactory product.

(b) *Type of Chamber*.—It is recommended that an air-tight chamber be used, the covering of which should be of some light material, *e.g.*, "malthoid." In the case of movable hoods, precautions should be taken to prevent ingress of air at the base of the hood, as, for example, by using compacted, moist earth around the bottom.

A number of small air-tight chambers is recommended in preference to one large one, so that fruit shall not be held for any length of time after cutting and before sulphuring. For example, when using 6ft. x 3ft. trays, the size of the chamber should be sufficient to accommodate a stack of about 15 trays with a clearance of about 6in. between the trays and the sides and top of the chamber. Trays should be staggered 6ins. when stacking.

A vent hole, 1in. in diameter, should be provided in the roof of the chamber close to the wall furthest from the sulphur fire when one fire is used, or in the centre of the roof where a fire is used at both ends of the chamber.

A movable slide, preferably of glass, is a desirable adjunct in order to view the conditions inside the chamber and to test the condition of samples of the fruit.

(c) *Quantity of Sulphur*.—From 6lbs. to 8lbs. of sulphur per ton of fresh-cut fruit should prove ample, and it is essential that the sulphur be dry in order to burn readily. The sulphur pit should preferably be located just outside at one or both ends of the chamber, with a free entrance into the chamber and a small inlet vent to the sulphur pit.

The sulphur should burn steadily during the time the fruit is in the chamber, and slight fumes should be apparent issuing from the vent hole. Should these fumes cease, inspect the sulphur pan. Either relight any unburnt sulphur or add more sulphur if none left. If the sulphur is all burnt before the expiration of the sulphuring period, it is an indication of excessive draught through the hood. In subsequent sulphurings reduce the draught by reducing the size of the inlet and exit vents, and examine the hood for general leakages. It is desirable so to regulate the draught that the requisite quantity of sulphur burn throughout the sulphuring period and be practically burnt out at the expiration of that period.

The weight of fruit in a charge should be ascertained by weighing the quantity of pitted fruit on two or three trays; the average per tray and the total weight per charge can then be obtained. Calculate the amount of sulphur necessary, weigh this and measure the volume in a container. Thereafter it would be sufficiently accurate to measure the same volume of sulphur each time a similar number of trays is sulphured.

(d) *State of Fruit*.—It is desirable to sulphur as quickly as possible after cutting, preferably within two hours. (Hence the desirability, under (b), of a number of small chambers.)

Fruit should be stacked from the bottom upwards in order in which it is cut. Freshly cut fruit absorbs sulphur dioxide more readily than that cut some time prior to sulphuring, and this arrangement of stacking allows the driest fruit to be in contact with the maximum density of warm sulphur fumes, thus tending to uniform sulphuring results.

(e) *Period of Exposure*.—Under average summer day temperatures four to six hours' exposure to the sulphur fumes is considered sufficient to preserve the color without over sulphuring; on very hot days four hours should be sufficient. The practice of leaving the fruit in the sulphur chamber over night is not advocated, as it frequently results in over sulphuring.

(f) *Characteristics of Sulphured Fruit*.—The filling of the cups with juice is not necessarily a reliable indication of satisfactory sulphuring, as fruit in this condition may frequently be over sulphured.

Correctly sulphured fruit is usually characterised by an easily detachable skin with distinct exudation of juice into the cup and a general evenness of color of the cut surface.

(g) *Drying*.—The sulphur dioxide content may be reduced by allowing trays to stand in the shade for one or two days after sulphuring before exposure to the sun, and this procedure is recommended in all cases where there is any suspicion of over sulphuring.

---

## FRUIT CROP ESTIMATES IN SOUTH AUSTRALIA, NOVEMBER, 1930.

---

[Compiled by GEO. QUINN, Chief Horticultural Instructor, from reports of District Horticultural Instructors.]

North of Adelaide, in the *Barossa, Clare, and Wirrabara areas*, the apple crop is very light, excepting in a few isolated instances, where the yellow varieties—mainly *Cleopatra*—are fair; around Williamstown a few from fair to medium crops of colored sorts are seen. Pears are light in all varieties, including the *William's Bon Christien*.

Quinces and nectarines are light. Peaches are only medium to light, varying with the sorts—very few clingstone sorts are grown. Most sorts of European plums are light, a few Japanese sorts alone showing a fair crop. Prunes are medium, and a few trees here and there heavily cropped being noticeably better than other sorts. Apricots are patchy; some trees good; others practically fruitless. On the whole, they will be well below normal. Almonds are mostly cropping well. Zante currants crop is mostly light; apparently lighter around Clare than in the lower Barossa areas. Wine grapes are showing quite good average crops in some vineyards, in others patchy from the effects of past drought. The general average will probably prove below normal, though prospects have been much improved by good late spring rains. Oranges and lemons are flowering and forming good crops, but many will fall in due course. Expect normal yield.

In the *Mount Lofty Ranges* apples have set a very light crop, though the principal export varieties—Jonathan, Cleopatra, Dunn's, and Rome Beauty blossomed well in most orchards. The yield is estimated in this, our principal apple producing area, at about 20 per cent. of a normal yield. Pears are patchy, the William's Bon Chretien being from light to fair only. The crop is probably 40 to 50 per cent. below normal yield.

Plums of Japanese sorts are very light, and most European varieties patchy. Good crops are showing on trees of Kirk, Greengage, Grand Duke, Giant Prune, D'Agen, Splendor, and old dark French prune varieties. Cherries are mostly light; Early Lyons alone being quite good. The crop generally is estimated at 75 per cent. of normal. Amongst berry fruits gooseberries are good, raspberries and loganberries promise well. Strawberries are promising good yields. These small fruits are only grown in quantities appropriate to local needs.

On the *Adelaide Plains and Southern areas* apples are promising a medium to light yield. Apricots generally are fair to good; nectarines good; peaches fair; and pears fair. Plums of most varieties are promising fair to good yields. Almonds, good average. Tomatoes, good yields generally in glasshouses. Citrus trees have bloomed freely, considering their drought debilitated condition, but the character of the crop of new fruit is problematical at present. Some of the latter sorts, such as Compuda and Late Valencia, have still a fair quantity of marketable oranges hanging. Grape vines of all sorts are looking well, and, judging from the bunches of flowers, there should be a medium crop borne in most vineyards.

In the *South-Eastern districts* apples have blossomed remarkably well, but the setting is distinctly poor, more particularly among the principal export varieties. Apricots (at Coonawarra) promise a good average yield, and the same remark applies to peaches. Pears are patchy, some sorts fair only, but on the whole not above 75 per cent. of a normal crop. Plums and prunes have a normal crop, and almonds are fair.

In the irrigated areas of the *Murray Valley* apricots generally are showing heavy crops, and, owing to spring rains, a fair amount of shothole fungus is noted on the fruits. Nectarines and peaches (Elberta) are mostly well laden. Pears (chiefly William's Bon Chretien) are again promising fair yields; and prunes, though not largely planted, are showing for good yields in some settlements. Almonds are carrying good crops. Orange trees have bloomed profusely, and are looking remarkably well for the coming crop. Generally speaking, a very important awakening in respect to the fertilising of citrus trees has taken place in these areas during the past three or four years, and the trees are now responding in proportion.

Amongst grapes, the Sultana crops are much below average, and look like very little above a 50 per cent. normal yield being gathered. Zante currants are up to average, and Gordos promise to exceed normal quantities. Doradillos are irregular, and mostly only fairly well cropped.

## SEED FROM CROP COMPETITIONS.

The following competitors in Crop Competitions have exhibited crops which, in the opinion of judges, will produce grain suitable for seed purposes:—

Competition. Competitor. Address. Variety.

### RUSSELL AND BUCCLEUCH—

A. J. Walker, Perponda—Felix.  
H. Sanders, Karoonda—Nabawa, Caliph.

### ALFRED—

G. E. Hyde, Paruna—Merriden.  
F. A. Hondow, Paruna—Free Gallipoli.  
A. E. Reichstein, Paruna—Nabawa.  
A. C. Webb, Paruna—Ford.  
A. A. Patterson, Paruna—Sultan.  
C. Wareing, Paruna—Nabawa.  
A. G. Petch, Meribah—Late Gluyas.  
A. A. Marsh, Meribah—Felix.  
A. R. Birch, Nangari—Gluyas, Nabawa.  
J. C. Auricht, Taldra—Gluyas, Late Gluyas, Caliph, South African.  
A. W. Traeger, Loxton—Sultan.

### ALBERT—

W. H. Todd, Caliph—Bald Early.  
T. C. Stott, Mindarie—Bald Early.  
P. J. W. Clonan, Halidon—Free Gallipoli.  
C. H. Russell, Halidon—Banee.  
G. H. Sutherland, Copeville—Sepoy, Sultan, Free Gallipoli.  
A. E. Carslake, Kumlara—Sultan.

### NORTHERN YORKE PENINSULA—

T. H. Trengove, Bute—Waratah.  
E. W. Clasohm, Arthurlton—Ford.  
H. E. Aldenhoven, Arthurlton—Sepoy.  
M. Yelland, Kadina—Waratah.  
H. Rodda, Thrington—Free Gallipoli.  
T. Rodda, Thrington—Nabawa.  
C. Rodda, Thrington—Nabawa.  
E. Yelland, Thrington—Faun.

### JERVOIS—

A. Spriggs, Cleve—Gluyas.  
C. McCallum, Budall—Gluyas.  
D. McCallum, Budall—Sultan.  
G. H. Branden, Budall—Nabawa.  
E. H. Pearce, Budall—Gluyas.  
W. F. Lake, Budall—Nabawa.  
F. Hauschild & Sons, Cleve—Bena.

### LE HUNTE—

J. G. Spiers, Wudinna—Caliph.

### CHANDOS—

E. E. Meagher, Murrayville—Free Gallipoli.  
C. and L. Fischer, Pinnaroo—Begum, Free Gallipoli.  
E. Neindorf, Parilla—Caliph.  
C. E. Moyle, Parilla—Sultan.  
J. H. and C. H. Spratt, Lameroc—Sultan, Waratah, Felix.  
C. L. Spratt, Lameroc—Waratah.

Competition. Competitor. Address. Variety.

CHANDOS—*continued.*

A. J. A. Koch, Lameroo—Sultan, Gluyas.  
C. E. Koch, Lameroo—Sultan.  
R. C. Jacob, Geranium—Free Gallipoli.  
Hardy Bros., Jabuk—King's Early.  
W. E. Beelitz, Jabuk—Nabawa, Sultan.

BUXTON—

N. B. Hancock, Kimba—Faun.

SOUTHERN—

E. W. Woolfit, Strathalbyn—Sultan.  
Thomas Bros., Monarto South—Nabawa.  
C. F. Altmann, Monarto South—Leatherhead.  
C. Brooks, Woodchester—Nugget.  
W. Bermingham, Woodchester—Caliph.  
C. A. Whittlesea, Langhorne's Creek—Nabawa.  
Whittlesea Bros., Langhorne's Creek—Dan.  
Pearson Bros., Brinkley—Dan, Nabawa.  
H. D. and E. G. Humphrey, Brinkley—Nabawa.  
A. B. Jaensch, Bletchley—Currawa.

MIDLANDS—

W. R. Woods & Sons, Mintaro—Bena, Federation.  
A. E. Scarfe, Mintaro—Free Gallipoli.  
J. Ross, Mintaro—Free Gallipoli, Sepoy.  
B. W. Blachford, Mintaro—Free Gallipoli.  
A. L. Sandow, Mintaro—Wannon.  
Keith Shunke, Manoora—Federation and Dan.  
H. Shunke, Mancora—Free Gallipoli.  
L. Thornby, Merilden—Free Gallipoli.  
A. J. Melrose, Mintaro—Free Gallipoli.  
J. S. Miller, Auburn—Federation and Nabawa.  
A. R. Bagshaw, Saddleworth—Dan.  
J. G. Rogers, Saddleworth—Dan and Nabawa.  
Crawford Bros., Saddleworth—Waratah.  
F. Coleman, Saddleworth—Free Gallipoli.  
G. & C. Frost, Manoora—Free Gallipoli.  
J. H. Torr, Farrell's Flat—Bena.  
S. Garrard, Merilden—Free Gallipoli.  
L. A. Martin, Farrell's Flat—Bena and Free Gallipoli.  
R. H. Martin, Farrell's Flat—Bena.  
A. E. Crossing, Farrell's Flat—Free Gallipoli.  
G. Miller, Farrell's Flat—Bena.  
Jas. Brereton, Hanson—Leak's Rust Proof.  
W. J. Woolacott, Hanson—Nabawa, Clarence, and Leak's.  
C. P. Turner, Hanson—Nabawa.  
Jas. Dempsey, Farrell's Flat—Federation.  
H. H. Davis & Sons, Riverton—Waratah.  
A. L. Frost, Riverton—Waratah.  
J. W. Kelly, Riverton—Waratah.  
A. G. Bright, Clare—Free Gallipoli.  
V. M. Lally, Clare—Free Gallipoli.  
W. S. McAuliffe, Buchanan—Nabawa.  
W. Armstrong, Buchanan—Free Gallipoli.  
L. V. Bell, Marrabel—Federation.  
R. & N. Hughes, Kapunda—Onas and Sultan.  
G. Hazel, Kapunda—Wanvan and Nugget.  
W. S. Kelly, Tarlee—Sultan, Currawa, and Sepoy.  
Molineaux Bros., Tarlee—Free Gallipoli.  
Clayton Dunn, Black Springs—Nizam.

## A NEW NOXIOUS WEED.

### THREE-CORNERED GARLIC (*ALLIUM TRIQUETRUM*).

[By EDGAR W. PRITCHARD, Dip. Econ., Botanical Assistant.]

The plant which is shown in the accompanying photographs is a native of Europe and was imported into Australia in the early days as a garden flower. Its strong garlic odor, however, makes it objectionable in many ways. Thus we find it all round the suburbs of Adelaide, and also in many country towns, growing vigorously in heaps of garden refuse on vacant blocks and rubbish tips. It has thus existed as a garden escape for many years. But, recently, Mr. C. H. Beaumont, Horticultural Instructor, has found it growing in the open and spreading widely in pasture land, chiefly in moist places, near Ambleside and Mount Barker. We have also had a specimen sent in for identification from Naracoorte. This shows that it is practically certain to become a dangerous noxious weed if not completely exterminated wherever it appears. For while its

strong garlic odor and flavor protect it from browsing animals, it has the power of spreading surely, if slowly, both by seeds and bulbs. There is no reason, in fact, why it should not become as great a pest as onion weed, which has for a long time been on the list of declared noxious weeds.

Three-cornered garlic usually grows in dense clumps, the piece in the illustration having been separated out to show the parts distinctly. The general habit and also the flower very much resembles the common snowflake, but it has the points of the petals turned outwards instead of inwards. There is also a green line down the middle of each petal. It is called "triquetrum" or "three-cornered" because the flower stem

is triangular in section. The leaves also have much the same shape on account of a very prominent wing, which runs up on one side of the flat leaf blade. Besides this, it can be distinguished from most other garden plants by its strong garlic odor when bruised.

It should be destroyed ruthlessly and thoroughly wherever it appears. For it is quite possible, at this early stage, to eradicate it completely without any prohibitive expense. The best means is to pull the clumps by hand when the soil is saturated with water in the winter. They should then be thrown into heaps and burnt, when dry, in the late spring or autumn.

By this means, the whole of the plant, including the young bulbs, will come away, whereas with grubbing or cultivating they are only scattered and given more room to flourish. If the plants have become too thick to allow pulling by hand to be a payable proposition, then clean fallow for one or, perhaps, two years is the only remedy.

---

## FUMIGATING TOMATO HOUSES WITH HYDRO-CYANIC ACID GAS TO DESTROY WHITE FLY (*Trialeuroides vaporarium*).

[By GEO. QUINN, Chief Horticultural Instructor.]

---

The house should be made as airtight as possible prior to fumigating it, as the value of the fumigation is increased or diminished in proportion to the chance of retaining the fumes. The ingredients generally used in carrying out the pot method are:—Potassium cyanide, 98 per cent. purity; sulphuric acid (commercial strength); pure water.

The generating vessels usually adopted are glazed, large-mouthed earthenware jars, which must not be used afterwards for any other purpose owing to the poisonous character of the chemicals.

In calculating the charge, 1oz. of the cyanide, 1oz. (fluid) sulphuric acid, and 3ozs. rain water are suggested in fumigating each 250 cubic feet of the space enclosed in the house. This can be calculated by multiplying together the length, width, and height of the house to the top of the vertical sides; then multiplying the length by the width, and the result by the height of the apex of the gable above the side walls, together, and dividing this result by two. Add the quotient to the previously obtained sum of the length, width, and height of walls, and divide the answer by 250.

## BUNGEY BROS., GRAIN and FORAGE MERCHANTS.

SPECIALISTS IN—Baled Lucerne Hay and Lucerne Chaff.  
Compressed Fodder and Baled Oaten Hay.  
DEALERS IN—Seed Wheat, Oats, Barley, Maize, &c.

HEAD OFFICE: 173, FRANKLIN STREET, ADELAIDE. 'Phone Cent. 988.  
Branch at Todd Street, Port Adelaide. 'Phone J 2190.  
Wholesale and Spice Grinding Mill, Symonds Place, Adelaide.

For instance, a house measuring 100ft. long, 30ft. wide, with 4ft. vertical walls, and a rise of 4ft. in height from height of walls to apex of gable, would contain 18,000 cubic feet of space. This would need 72ozs. ( $4\frac{1}{2}$ lbs.) cyanide,  $4\frac{1}{2}$ lbs. sulphuric acid, and 216ozs., or 10 $\frac{1}{2}$  pints, of rain water to give it a fumigation.

One fumigation is not sufficient; it may kill all the winged or larval insects, but not the eggs. A second treatment two or three weeks later, when these eggs have hatched, should make a good job of the killing if the house be reasonably airtight. The procedure of fumigating is best done after the sun goes down or, at any rate, when it does not shine on to the house.

A number of 1gall.-sized glazed jars should be procured. These will each take about 8ozs. charge of cyanide and acid with the necessary water. A board lid is also necessary to lay loosely on top of the jar as soon as the cyanide is dropped into it. This avoids splashing and diffuses the fumes. When about to fumigate, mix the acid and water in the jars, taking great care to put *the water in first*, then gently stir with a stick whilst the acid is added slowly.

Place these jars at regular intervals along the main track through the house. The charges of cyanide should be wrapped or screwed up in one or two thicknesses of newspaper and be placed ready with the board lid alongside the pots. If the house is a long one, say, 100ft. or over, and has a door at each end, two persons should do the charging, both starting near to the middle, and moving back towards their respective doorways, simultaneously dropping the papers containing the cyanide into the pots, clapping on the lids as quickly as possible as they pass out of the house, and close the doors, which have been left wide open whilst the men are in the house. The house should be kept shut up for not less than one hour, but may be left longer, and afterwards both doors and any other available vents at the ends or sides should be opened for an hour, particularly if there is no breeze blowing, before anyone enters.

When the pots are removed, the residues in them should be buried deeply, but not close to trees or other crop plants. The pots should be washed out carefully at the same time, and be stored upside down where no one can handle or make use of them. It is a good plan to twist a galvanized wire handle around the neck of each one to avoid having to hold the pot directly with the hands. This precaution is desirable to avert the burning action of any dilute acid, as well as to avoid the poisonous nature of the cyanide.

The utmost care is required in handling and storing cyanide and sulphuric acid. The fumes of cyanide must not be breathed in; hence, keep the nostrils away when opening cyanide containers and charging or handling generators if any of the gas is still evolving.

The hands must not be put to the mouth when handling cyanide, and all weighing and cracking—the lumps used should be from the size of a pea to a walnut—should be done in the open air with a handkerchief or some protection against spattered chips or particles of the poison reaching the mouth. Pieces the size of a small seed will poison fowls, &c., and a man could collect enough particles under his finger nails to poison himself if conveyed to the mouth. Hence, the need for care and cleanliness when it is handled, always washing the hands immediately afterwards.

The sulphuric acid is very corrosive to the skin or clothing, hence, care must be taken to avoid splashes. If any burns occur, promptly sponge the spots with liquid ammonia or use carbonate of soda or even lime to neutralise the acid.

There are other methods of generating hydrocyanic acid gas, and possibly the flake form of calcium cyanide, which needs only to be placed in drills made in the damp soil between the rows of plants to cause an evolution of the gas, would prove effective and be more readily handled if it were available locally.

## AGRICULTURAL BUREAU CONFERENCES.

### EYRE PENINSULA—(KIMBA.)

A Conference of Branches situated on the eastern side of Eyre Peninsula was held at Kimba on October 6th under the auspices of the Kelly Branch.

Mr. C. Freeth presided over the Conference, which was formally opened by Mr. P. H. Jones (Advisory Board of Agriculture). Mr. Jones referred to the valuable part which Conferences played in the agricultural development of South Australia. Representatives of Branches were not only given an opportunity of meeting members of other Branches, but they were also able to seek the opinion and advice of technical officers of the Department on problems which constantly confront the farmer. He paid a tribute to the work of the Agricultural Instructors and stated that as a member of the Advisory Board of Agriculture he was able to obtain first-hand information as to the valuable work which was being accomplished by these officers. He was convinced that, with the present grave position of the wheat and wool markets, the time was now opportune for stimulating these industries by scientific methods of production. The farming of districts represented at the Conference must necessarily continue as a wheat-growing proposition. In this respect it would be difficult to assess the full value to farmers of such varieties of wheat as Ford, Daphne, Caliph, Sultan, and Felix, all of which were products of Roseworthy College. In fact, of the nine most extensively grown wheats at the present time, five originated at Roseworthy. Work like this should be encouraged to the utmost.

Papers were read by Mr. R. F. Mayfield (Kelly) on "Some Problems of the Eyre Peninsula Farmers"; Mr. J. S. Atkinson (Kelly), "Wheatgrowing and National Welfare"; Mr. J. E. Beinke (Kelly), "Growing Wheat under a Low Rainfall"; Mr. S. C. Johnson (Pinkawillinie), "The Conservation of Fodder"; and Mr. T. Harris (Kelly), "Poultry on the Farm."

Numerous questions were asked, and replies given by Prof. Perkins (Director of Agriculture), Messrs. W. J. Spafford (Deputy Director), R. H. F. Macindoe (Deputy Chief Inspector of Stock), and H. B. Barlow (Chief Dairy Instructor).

Addresses were given by Messrs. W. J. Spafford on "Wheat and its Diseases and Means of Combating same in Mallee Districts" and Mr. H. B. Barlow on "Dairy Cattle on Mallee Farms." Mr. Spafford also gave a review of experiments with varieties of wheats in mallee country.

The following resolutions were carried:—

1. "That the next Conference be held at Cleve."
2. "That this Conference strongly protests against the increased exchange on cheques on Eyre Peninsula."

### CONFERENCE AT WUDINNA.

On October 9th a Conference, embracing all Branches on Eyre Peninsula, was held at Wudinna, when Mr. A. W. H. Barns presided over a large attendance of representatives from many parts of the Conference district.

The Conference was opened by Mr. P. H. Jones, who stated that never in the history of primary production was there more need than now for strict economical farm management. He was of opinion that all members of the Bureau should be loyal in their support for a continuance of departmental guidance, as there were few who failed to recognise the difficulties which hampered the State, and in South Australia particularly primary production was the only avenue of escape. On a previous visit he had referred

to the important part which the newer areas would play in the production of the State and, although seasonal conditions had seriously handicapped the yields, he was confident that, with a return of better rainfall and with the continued improvement in farming methods, that expectancy would be realised. Many farmers had secured quite satisfactory results in respect to the maximum production of their holdings, but he drew attention to the fact that in county Buxton, in 1926-27, 57 farmers secured a return approximating the average (9.54bush.), 97 obtained over the average and up to 18bush., while 42 farmers secured less than the average, and some even down as low as under 3bush.

Papers were read by Mr. A. J. Shepherd (Wudinna) on "Farm Economy," and Mr. E. H. Edmonds (Pygery) on "Cost of Production."

Questions were asked by various Branches, replies being given by Prof. Perkins (Director of Agriculture), W. J. Spafford (Deputy Director), H. B. Barlow (Chief Dairy Instructor), and R. H. F. Macindoe (Deputy Chief Inspector of Stock).

At an evening session addresses were given by Mr. Barlow on "Dairy Cattle on Mallee Farms," and Mr. Macindoe on "Ailments and Injuries of Livestock."

The following resolutions were carried:—

1. "That the next Conference be held at Wudinna."
2. "That the Department of Agriculture be requested not to hold Conferences or visiting days at the Experimental Farm on public holidays."
3. "That the Department of Agriculture be requested to supply two pure bred milking Shorthorn cows to the Minnipa Experimental Farm for the purpose of breeding stock for distribution throughout this and the surrounding districts."
4. "That the South Australian railways be requested to reduce the freight on wheat and super on the Eyre Peninsula lines by 25 per cent. to compensate for the low price of wheat."
5. "That this Conference requests the Advisory Board of Agriculture to approach the wheat merchants with a request to allow farmers to sell their wheat in sound second-hand bags."
6. "That Branches on Eyre Peninsula co-operate in an endeavor to present a request to superphosphate manufacturers and distributors on Eyre Peninsula to allow farmers a reduction in the price of super of the amount of commission paid to agents, provided that farmers sent in their orders direct to manufacturers."
7. "That the Government devise some scheme of encouraging the breeding of draught horses in the State."
8. "That the Government be approached to assist the farmers by granting them concession freights on approved flock rams procured for the purpose of building up their flocks."

### NON-IRRIGATED FRUIT AREAS CONFERENCE.

Branches of the Agricultural Bureau situated in the non-irrigated fruit areas of the State held their Conference at Angaston on November 4th.

Mr. W. Patching presided over the Conference, and in the course of the opening address, Mr. H. N. Wicks (Vice-Chairman of the Advisory Board of Agriculture) stated that, whilst nobody would deny the unenviable position of many agriculturists, he was firmly of the opinion that the fruitgrower was in an even more unenviable position. Everywhere there was a desire for more research work to solve some of the pressing problems of the growers, and it was a matter for extreme regret that at such a time the financial position was such as would not permit of these necessary investigations. Present indications pointed to the fact that the fruitgrower would have to take lower prices for his produce and, with this aspect in front of him, the only solution of the problem seemed to be in the direction of increased production.

Papers were read by Mr. W. Goldsack (Blackwood) on "Orchard Practices in America"; Mr. J. B. Harris (District Horticultural Instructor), "White Oil Spray

and Manuring of Apricot Trees'; Mr. F. E. Rix (Williamstown), "Profitable Utilisation of Waste Orchard Products."

Mr. W. C. Johnston (Agricultural Instructor) delivered an address on "Weeds of the District," and questions on a variety of subjects were answered by officers of the Department of Agriculture.

Resolutions were carried as under:—

1. "That the next Conference be held at Clare."
2. "That this Conference considers that all petrol used on farms and orchards should be free of all tax, and, if not, a rebate should be allowed."
3. "That this Conference, representing the non-irrigated fruitgrowing areas, recommends to the Dried Fruits Board that 'buck' currants, used in manufacturing processes not competing with other dried fruits, be allowed to be sold without comprising portion of either home or export quota."

## If you can't grow vegetables

*and you can't buy them, you will  
certainly need a stock of Swallow  
and Ariell's Compressed Vegetables.*

**THEY'RE** equal in every way to fresh, as only water is removed—true flavour is retained. One pound goes as far as ten of the fresh, so that they're easily carried. Store them as long as you like—with a few packets at hand you need never be short of health-giving vegetables.

### Here's the Range of Compressed Vegetables.

Carrots, Parsnips, Turnips, Onions, and mixed—Compressed and supplied in  $\frac{1}{4}$ lb. cartons and 1lb. tins.

Tomatoes and Rhubarb—Compressed and supplied in  $\frac{1}{4}$ lb. cartons.

Beetroot—Loose, in 1lb. tins.

Mixed Vegetables—Loose, in  $1\frac{1}{2}$ oz. packets.

# SWALLOW & ARIELL'S COMPRESSED VEGETABLES

## ADVISORY BOARD OF AGRICULTURE.

---

A meeting of the Advisory Board of Agriculture was held on Wednesday, November 26th, 1930, when the following members were present:—Messrs. H. N. Wicks (Vice-Chairman), A. M. Dawkins, P. J. Bailly, A. J. Cooke, P. H. Jones, S. Shepherd, R. H. Martin, Dr. A. E. V. Richardson (Director Waite Research Institute), Mr. W. R. Birks (Principal Roseworthy Agricultural College), Professor Arthur J. Perkins (Director of Agriculture), and Mr. H. C. Pritchard (Secretary).

Apologies were received from Messrs. F. Coleman, J. W. Sandford, H. S. Taylor, and A. L. McEwin.

*New Member.*—The Chairman extended a cordial welcome to Mr P. J. Bailly as a member of the Board. Mr. Bailly was appointed in lieu of Mr. H. A. Mayfield, who had resigned.

*Controlling Fruit Crops.*—Mr. Geo. Quinn (Chief Horticultural Instructor) submitted the following report on a resolution of the last Conference of Hills Branches that steps be taken to investigate the possibility of controlling fruit crops by systematic manuring:—“From what I can recall of the discussion, this resolution and the subject dealing with the change of wood buds into fruit buds are relevant to each other, both having for their object the regulating of the cropping habits of apple trees. I understand Mr. Wicks, of Balhaunah, and Mr. Basey, of Cherry Gardens, have been manuring small plots of apple trees for the last year or so with sulphate of ammonia with this object in view. We have also added this treatment to a plot of apple trees devoted to pruning and thinning trials at Blackwood Orchard, and which have crop regulation as their objective. The unknown factors, however, seem to be what is the best fertiliser to use, and when, and how should it be applied to the land. Assuming nitrogen to be the crop-limiting factor with apple trees—as we believe it to be with orange trees—we are in doubt as to when it should be applied to most effectively meet the needs of the developing flower buds. In the plots or rows consisting of equal numbers of apple, pear, and peach trees growing in the permanent manure trials at Blackwood Experiment Orchard since 1908, the results from annual spring dressings of fertilisers, whether applied singly or in combinations, have thrown very little, if any, light on this subject up to date. Possibly, our dressings have not been sufficiently heavy or have not been applied in the best manner or at the most desirable time to assure the roots receiving benefit therefrom. Anyway, up to the present we must confess to appearing to be ‘groping in the dark’ in respect to manuring deciduous fruit trees when working along ordinary prescribed channels of procedure.”

*Change of Wood Buds into Fruit Buds.*—Mr. Quinn submitted the following report on this matter, which was the subject of a resolution passed at the Hills Conference:—“The matter of the determination of the period of the year when the flower buds on fruit trees begin to differentiate from the ordinary leaf buds has been under scientific investigation in U.S.A. and Europe from time to time during the past 30 years. Those directed towards the apple in U.S.A. have been carried out at the respective University Experiment Stations as follows:—By Professor Goff, of Wisconsin, in 1899, on a variety called Hoadley; by Drinkard, of Virginia, in 1909, on Duchess of Oldenburg apple; by Bradford, of Oregon, on Yellow Newtown in 1912; and by Tufts and Morrow, of California, on the Gravenstein apple in 1923. More latterly, Dr. Swarbrick, of the Long Ashton Horticultural Research Station, Bristol, England, conducted further research into this subject. In all of these researches the histological structures of the buds were carefully studied, and micro-photographs prepared showing in clear detail the various stages of differentiation and development of the primordia of the floral organs. Summed up, differentiation was first noticed in the flower buds of the respective apples by the

above-named investigators on the following dates:—By Goff, June 30th, 1899; Drinkard, June 30th, 1909; Bradford, early July, 1912; Tufts and Morrow, June 11th, 1923; Swarbrick, late June, 1927. Although, as far as I can ascertain, no work has been done in Australia on this phase of apple bud growth, these periods indicate that we may expect differentiation of the flower buds to be detectable in Australia towards the end of December or early in January. As, however, our climate, and the varieties of apples we grow, may each exercise some influence on these developments, considerable variations in the equivalents of the American or European dates may be eventually found. A study of this nature involves not only a good working knowledge of the morphology of the apple blossoms, but necessitates the possession of great skill in the technique of cutting, staining, and generally preparing vegetable tissues for microscopic specimens to enable critical examinations to be conducted. In view of these facts, this is work for a botanist trained in vegetable histology and microscopic technique. If the Director of the Waite Agricultural Research Institute could allocate the study to a trained assistant, I could arrange to collaborate by the provision of seasonal material from the Blackwood Experimental Orchard, where trees of a very wide range of varieties of apples or other fruits are available. It would seem that a more exact knowledge of the times of the year when the various stages of development take place in flower buds in apples may prove very valuable in formulating any experimental work, aiming at the control of the irregular cropping habits exhibited by apple and other fruiting trees."

Dr. Richardson promised to collaborate with the Department of Agriculture in conducting experiments as proposed. He suggested that Mr. Quinn's staff gather specimens of twigs and retain them in a fixing bath at the Blackwood Experimental Orchard until the investigations could be commenced.

*State Bank at Alawoona.*—The resolution of the Murray Lands Conference that a branch of the State Bank be established at Alawoona to help the development of the district, was referred to the State Bank. The General Manager intimated that the matter of opening a branch of the bank at Alawoona had been reconsidered, and it had been decided to take no action at this stage owing to existing financial conditions.

*Destruction of Foxes.*—A report had been obtained from the Vermin Board with reference to the Hills Conference resolution requesting that the month of March be set aside for the simultaneous destruction of foxes, and that it be an offence to liberate any fox. The report, in effect, states that foxes are included as vermin in the definition of "vermin" in the Vermin Act. The Act provides that all district councils, vermin boards, and associated boards shall within their respective districts strictly enforce the provisions as to the destruction of vermin. Further, every owner and every occupier of any land shall at all times and at his own cost and expense destroy all vermin upon such land, and upon the half width of all roads adjoining the same. Any person who

lets loose any vermin or permits any vermin to be let loose, in any part of the State, shall be liable to a penalty for each offence not exceeding £100 or to be imprisoned for a term not exceeding six months with hard labor. Vermin Acts provide for the simultaneous destruction of vermin. The periods fixed within the counties of Adelaide, Hindmarsh, and Sturt are from February 15th to March 14th, and from July 15th to August 14th in each year. The report was received, and the Secretary was asked to communicate same to the Mount Pleasant Branch, pointing out that possibly their requirements were already covered by the Act.

*Climatological Station at Wudinna.*—The request of the Wudinna Conference that Wudinna be reinstated as a climatological station was referred to the Divisional Meteorologist, who submitted a report on the subject, at the conclusion of which he stated that "while appreciating the point of view of Wudinna residents, I regret that limitations, imposed by economy, amount of telegraph business allowed, and also by the size of our weather bulletin, preclude the reinstatement of Wudinna in the list of daily telegraph rain reporting stations." The report was received, and the Secretary was asked to advise the Wudinna Branch accordingly.

*Division of Mallee Lands Conference District.*—On the motion of Mr. P. H. Jones, seconded by Mr. S. Shepherd, it was decided to accept the suggestion that the district be divided by a line running north and south between Halidon and Mindarie. That, it was considered, would give an almost equal division of Bureau Branches on each side, and would be convenient so far as distance of travelling to Conferences was concerned.

*Buck Currants.*—The following resolution was received from the Conference of Non-irrigated Fruitgrowing areas:—"That this Conference representing the Non-irrigated Fruitgrowing areas recommends to the Dried Fruits Board that buck currants be used in manufacturing processes not competing with other dried fruits and be allowed to be sold without comprising portion of either home or export quota." It was decided to refer the matter to the Dried Fruits Board.

*Export of Pig Meat.*—The following resolution was received from the Narridy Branch:—"That we ask the Advisory Board what has been done in regard to the exporting of pig meat from South Australia during the last two years." It was decided to advise the Branch that an experimental shipment was being prepared at present and to seek further information from the Victorian Department of Agriculture on shipments that had been made from that State.

*Concession Freights on Flock Rams.*—The Minister stated that no action will be taken in reference to the request of the Wudinna Conference that concessions be given for freights on approved flock rams.

*Experimental Farms.*—Petitions were received from residents at Mangalo, Wudinna, Ceduna, Cungi, Wirrulla, Minnipa, and other centres, requesting the Honorable Minister to conduct the Minnipa Experimental Farm on a commercial basis until such time as the financial condition of the State will warrant the resumption of experimental and seed wheat distributing operations. It was decided that a deputation consisting of Messrs. F. Coleman, A. M. Dawkins, R. H. Martin, and P. H. Jones, wait on the Minister of Agriculture regarding this matter.

It was decided not to take any further action in connection with a resolution of the Kyancutta Branch dealing with the closing of experimental farms.

*Agent's Commission on Superphosphate.*—As requested by the Board at the October meeting, Mr. Shepherd reported on the Wudinna Conference resolution as follows:—"With many others I feel that superphosphate should be distributed direct to the farmer without the unnecessary commissions to distributors and agents, which tend to restrict rather than augment the full use of this article. Acting on lines of direct supply to farmers, one small concern in Victoria has in three years of manufacture reached an output of 80,000 tons per annum. This concern operates as follows:—To their shareholders they make a rebate at a rate determined by profits on the basis of per ton per share, viz., every £5 share carries a rebate for one ton of super, which has

worked out at 7s. 10d. per share covering a period of three years. Assuming that the number of tons purchased by a shareholder is greater than the number of shares he holds, the balance purchased above the share quota participates in a minor rebate at the rate of 3s. per ton, and if the two quotas combined exceed 100 tons, a further rebate of 2s. 6d. per ton is allowed. Thus:—

|                                                 |     |         |
|-------------------------------------------------|-----|---------|
| One ton for each share held would cost .. . . . | —   | £4 15 0 |
| Less—                                           |     |         |
| Cash on receipt of invoice .. . . .             | 5 0 |         |
| Rebate for 1930 (in 1929 it was 8s.) .. . . .   | 7 6 |         |
| If purchased in 100 ton lot .. . . .            | 2 6 |         |
|                                                 | —   | 0 15 0  |
| Net price per ton .. . . .                      |     | £4 0 0  |
| One ton above the share quota .. . . .          |     | 4 15 0  |
| Less—                                           |     |         |
| Cash on receipt of invoice .. . . .             | 5 0 |         |
| Minor rebate .. . . .                           | 3 0 |         |
| If purchased in 100 ton lot .. . . .            | 2 6 |         |
|                                                 | —   | 0 10 6  |
|                                                 |     | £4 4 6  |

(In both cases where the farmer returns the bag a corresponding 7s. 6d. per ton is deducted.)

The practice in South Australia has been to allow only 2s. 6d. per ton on receipt of invoice or 30 days and 5s. for cash with order. As "cash with order" is not a usual business practice with farmers, it means a gift of 2s. 6d. per ton to the distributors in addition to their trade allowance. The presence of an army of canvassers and a staff of unskilled inspectors does not add one ton to the aggregate consumption. While it might increase the individual factory output, according to the energy and popularity of the inspector, it must add to the cost. I feel that the delegates of the Wudinna Conference have ample grounds for complaint, and that the price could be considerably reduced, as the old established concerns should at least be able to beat the younger and probably less experienced concerns like that quoted above. Messrs. F. Coleman, S. Shepherd, and P. H. Jones were appointed to interview the superphosphate companies regarding this matter.

*Investigations into the cost of Wheat Growing.*—The Murray Lands Conference moved—"That the Department of Agriculture be requested to continue to carry on the work of investigating costs relating to the growing of wheat." This was referred to the Director of Agriculture, who supplied the following report:—"It is satisfactory to learn that the Murray Lands Branches are interested in the work we have been carrying out relative to the cost of growing wheat. In this connection I wish to point out that for eight successive seasons we have investigated this question on the Turretfield Experimental Farm, and whilst the results secured there are dependable, mainly because the manager is a very competent man, they nevertheless do not correspond to the average position on South Australian farms. At Turretfield both the cost of management and the cost of labor are paid for in cash at standard rates. On the average farm, little or no hired labor is availed of, the great bulk of the manual work being carried out by the farmer and his family. It is therefore extremely difficult to determine the actual cost of growing wheat in these circumstances, whilst it is comparatively a simple matter to determine the labor income of the farmer and his family. I may say that at the present time we are investigating the cost of growing wheat on one mallee farm, and

the results will be published shortly. My own opinion is, however, that in order to get really representative results on the subject, it would be necessary to keep the accounts of several individual farms placed in typical wheat-growing districts of the State, and in each case these accounts should be kept over periods of not less than three successive years. Roughly speaking, this would involve:—Six farms on Eyre Peninsula; three farms representative of the Lower North, including counties Victoria, Daly, Stanley, Burra, and Kimberley; three farms in counties Albert and Alfred; three farms in counties Russell, Buccleuch, and Chandos; three farms on Yorke Peninsula; three farms over the rest of the Central Statistical Division; three farms for counties Buckingham and Cardwell. This, of course, would involve some addition to the existing clerical staff, which I am afraid in present circumstances is very difficult to expect. I mention it, however, as an ideal in a very important matter, and I hope to have the support of the Board should it at any time prove possible to secure the required assistance. I may say that such investigations should not, in my opinion, be confined to wheat, but should be extended to all our major agricultural operations, together with any minor operations that appear to have economic importance for this State." The Board supported the views of Professor Perkins, and it was decided to bring the matter up in six months' time for consideration.

*Open Season for Opossums.*—The Hills Conference resolution requesting that there be no open season for opossums and that landholders be the only persons allowed to take opossums on their own property, was brought under the notice of the Minister, who intimated that under the present Act no person has any right to take opossums on any property without the consent of the owner or occupier, and there was no intention of having an open season for opossums for some time.

*Veterinary Officers.*—The following resolution was received from the Narridy Branch:—"That this Branch ask the Advisory Board of Agriculture what can be done in regard to the appointment of a veterinary officer to the Northern Areas?" It was decided to forward the resolution to the Honorable the Minister of Agriculture.

*Enforcement of Regulations Regarding Control of Codlin Moth.*—Resolution from Blackwood Branch:—"That the regulations relating to the control of codlin moth be vigorously enforced, with special reference to neglected orchards." It was decided to transmit the resolution to the Minister.

*Petrol Used on Farms.*—The Non-irrigated Fruit Conference considered that all petrol used on farms and orchards should be free from all tax, and if not, a rebate should be allowed. The matter was deferred until the next meeting.

*Next Meeting.*—It was decided that the next meeting of the Board be held on the last Wednesday in January.

*Life Membership.*—Life membership of the Agricultural Bureau was conferred upon Messrs. W. O. Eime and J. A. Pratt, members of the Blyth Branch.

*New Members.*—The following names were added to the rolls of existing Branches:—Pinnaroo Women's—Mrs. W. Williams, Mrs. Hill, Mrs. A. J. Young, Miss K. O'Loughlin; Wallala—R. Nottle, S. Morgan, P. Duncan; Mount Barker—A. A. Paech; Mypolonga—Arthur Milde; Modbury—R. E. Mortimer, B. C. Mortimer; Eudunda—C. W. E. Ziegeler, A. B. Sieber; Beetaloo Valley—A. Head, C. C. Cox; Parilla Women's—Mrs. R. Curtis; Strathalbyn—S. H. Foreman, R. M. Tucker; Yandiah—W. Huddleston; Laura—F. T. Acott, R. Cornish, T. A. Kleinig, J. Reichstein; Pinkawillinie—M. McMahon; Pygery—Wm. Foster, H. Woodrup; Mount Barker—L. Bell, O. Kuchel; Millicent Womens'—Mrs. H. Ey, Mrs. A. Oberlander, Mrs. T. Latter; Yantanabie—C. Olsen; Alawoona—P. Masters; Clare—H. F. Hicks; Cungenah—R. Robertson; Narridy—V. J. Button; Penola—H. B. Wilson; Greenock—E. Heinze, M. Bolt; Parilla Women's—Mrs. Andrews; Clarendon—A. White; Millicent—T. N. Bell, F. N. White, R. A. Hateley, L. Hateley, E. Hutchesson, C. Butchesson, L. Hutchesson; Warcowie—C. Wheadon, A. Faulkner, E. Sanders.

**DAIRY AND FARM PRODUCE MARKETS.**

A. W. SANDFORD & Co., LIMITED, reported on December 1st, 1930:—

**BUTTER.**—Production for the month of November kept up remarkably well, due to the fact of fairly frequent rains received keeping the feed going in some parts and preventing the rapid drying off in others. The quantities of cream and butter received at the various factories was heavier than for several seasons, and export of the surplus butter was made each week to London. Prices were lower than have ruled for many years past, and the same applies to all world markets, so that it was not unexpected. Fortunately, London buyers absorbed all offering, so that at no time was there a glut in any of the Australian centres. With the approach of warmer weather, supplies are now cutting back; but there should be sufficient butter produced locally for all local requirements—at any rate until the end of the year. Choicest creamery fresh butter in bulk, 1s. 1½d.; prints and delivery extra. Second and third grades, 11½d. (these prices are subject to the stabilization levies); best separators, 10d. to 11d.; well-conditioned store and collectors', 7½d. to 8½d. per lb.; pastry lots lower.

**EGGS.**—The production in this line also was well maintained, although the peak period was touched in October, and there has been a steady lessening since, which is only to be expected with the advance of the season. With the warmer weather approaching affecting the quality, and with packing for export almost finished, values weakened. Ordinary country eggs, hen 5½d. per dozen; duck, 6½d. per dozen; infertile higher.

**CHEESE.**—The South-Eastern factories this year have produced record quantities, which have been marketed in Adelaide and Victoria, and so far stocks have been kept fairly well cleared. Western Australian buyers have purchased fairly regularly each week from the Adelaide merchants, but now that State's operations are being limited each year with the increasing production within their own borders. New makes, large to loaf, 6½d. to 6½d. per lb.; semi-matured and matured, to 11d. per lb.

**ALMONDS.**—Slightly better supplies came to hand in November, and these were cleared to local purchasers and rates continued steady. Brandis, 7½d. to 8d.; mixed softshells, 7d. to 7½d.; hardshells, 4d. to 4½d.; kernels, 1s. 6d. to 1s. 7d. per lb.

**HONEY.**—The new season's "take" is being marketed now, and as there was a carry-over from the previous season, values weakened, and the demand continued very dull. Prime clear extracted in liquid condition, 3½d. to 3½d.; best quality candied lots, 2½d. to 3½d.; second grade, 1½d. to 2d.

**BEESEX.**—Limited supplies came to hand and were cleared from week to week, values at present being 1s. 4½d. to 1s. 5½d. per lb., according to sample.

**BACON.**—As usual in the warmer weather, the consumption of bacon declines, but an improved demand is being shown for hams and bacon factory small goods, so that the output from the factories is being kept fairly well cleared. There was an easing in prices recorded in sympathy with the lower rates ruling for the live hogs. Best local sides, 9½d. to 10d.; best local factory cured middles, 9d. to 9½d.; large, 7½d.; local rolls, 9½d. to 10d.; Geo. Farmer's "Sugar Cane" brand hams, 1s. 2d.; local, 1s. to 1s. 0½d.; "Sugar Cane" brand lard in packets 11d., in bulk 10d. per lb. Local lard, 10½d. per lb. in prints.

**LIVE POULTRY.**—As usual with the nearer approach of Christmas, supplies of poultry are showing an increase, but a big proportion of the birds marketed, however, are not altogether suitable for table purposes, many consignments consisting of old and White Leghorn hens. So far the demand has kept up well, but buyers are keener for prime-conditioned stock than for the lighter sorts. Breeders would be well advised to fatten up stock before marketing, especially cockerels, turkeys, geese, and ducks, as it amply repays for the attention given in this way. We advise consigning. Crates loaned on application. As this is our last report for the year 1930, we would extend the best of Christmas greetings to all and wish that the year 1931 will be more prosperous for all concerned in this State. Prime roosters, 4s. 6d. to 5s. 6d.; nice-conditioned cockerels, 3s. 6d. to 4s. 3d.; fair-conditioned cockerels, 2s. 9d. to 3s. 4d.; chickens lower. Heavy weight hens, 3s. to 3s. 6d.; medium hens, 2s. 3d. to 2s. 9d.; light hens, 1s. 6d. to 2s.; couple of pens of weedy sorts lower. Geese, 4s. 6d. to 6s. 6d. Prime young Muscovy drakes, 4s. 6d. to 5s. 9d.; ducks, good conditioned, 3s. 9d. to 4s. 3d.; ducks, fair condition, 2s. 3d. to 3s.; ducklings lower. Turkeys, good to prime condition, 9d. to 1s. per lb. live weight; turkeys, fair condition, 7d. to 8½d. per lb. live weight; turkeys, fattening sorts, lower. Pigeons, 6½d. each.

**POTATOES.**—New Western Australian Delawares, 7s. to 8s. per cwt.

**ONIONS.**—New white, 6s. per cwt.

## RAINFALL TABLE.

The following figures, from data supplied by the Commonwealth Meteorological Department, show the rainfall at the subjoined stations for the month of, and to the end of November, 1930, also the average precipitation to the end of November, and the average annual rainfall.

| Station.                          | For Nov. 1930. | To end Nov. 1930. | Average to end Nov. | Average Annual Rain-fall. | Station.                      | For Nov. 1930. | To end Nov. 1930. | Average to end Nov. | Average Annual Rain-fall. |

## AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

### REPORTS OF BUREAU MEETINGS.

#### SOUTH-EAST DISTRICT.

#### LUCERNE CULTIVATION.

##### THE CULTIVATION OF LUCERNE.

The following paper was read by Mr. W. H. Downes (District Dairy Instructor) at a meeting of the Mount Gambier Branch held on August 8th:—Lucerne is perhaps one of the oldest and most widely cultivated fodder crops known to mankind, being recorded in ancient history as far back as 490 B.C. At the present time it is extensively grown in most parts of the world, but principally throughout the United States, certain temperate portions of Canada, South America, Mexico, along the Mediterranean shores of Northern Africa, South Africa, Southern Europe, practically all parts of Asia, and is one of the leading fodder crops in the Commonwealth.

##### SUITABILITY TO AUSTRALIAN CONDITIONS.

In Australia the acreage under lucerne is steadily increasing each year, and it has now been proved in certain districts previously deemed unsuitable, and where for that reason it had never been given a trial, that lucerne will do remarkably well. This shows that it is a fairly hardy plant, capable of adapting itself to a wide range of conditions, in regard to soil and climate.

##### ITS VALUE AS A FODDER CROP.

Lucerne has been very correctly designated the "King of Fodders," for, judging by its ever-increasing popularity as a stock food, the name appears to be well merited. There are a number of reasons why lucerne should be even more extensively cultivated, always providing the conditions are suitable, and it would pay many farmers and stock-owners handsomely to give it a trial by planting a portion of their property with this wonderful fodder. Lucerne is of special value on account of the fact that it grows most vigorously during summer, at a time when green feed is rarely plentiful. A few acres of lucerne may be the means of saving livestock, for frequently working horses have been restored to health, ewes pulled through a bad spell, or cows kept in profit during a dry season, when lucerne has been available. It has also proved invaluable as a means of providing reserves of fodder, in the form of hay or silage, to carry farmers over a lean period, by systematically putting aside one or two cuts out of the four, five, or possibly six cuts obtained in a plentiful season.

##### PRINCIPAL RECOMMENDATIONS.

(1) It is a profitable crop, and should considerably enhance the land value and carrying capacity of holdings. (2) It excels most other crops, generally speaking, in yield per acre, feeding value, and its ability as a drought-resister and soil enricher are well known. (3) It can be utilised in various ways, making excellent hay, silage, or in its green state either by cutting or grazing. (4) The continual cutting of the crop tends to minimise weeds. (5) In comparison to its yield, the costs associated with lucerne cultivation, harvesting, and machinery required, are not excessive when once established. (6) It is eminently suitable for feeding to all classes of farm stock, viz., horses, cattle, sheep, pigs, and poultry. (7) The risks of fire, ever present in the case of ripe cereal crops, or hay in stacks, are considerably lessened when lucerne is the principal forage crop grown on the farm. (8) Being a perennial, it should not require replanting for a number of years, particularly if the grower has been careful in his methods of treating and harvesting the crop.

## FEEDING VALUE OF LUCERNE.

If the crop has been harvested correctly, the entire plants are utilised and assimilated by stock, so that, generally speaking, there should be practically no waste. The proportion of digestible protein (organic nitrogenous compounds) to carbohydrates (starch) is fairly high, in comparison to other foods, being one to six. This constitutes what is termed a narrow ration, and when lucerne is mixed with fodders of wider feeding ratio, or, in other words, lower in protein content, the ration is considerably enriched, thereby tending to make animals more healthy, productive, and being especially suited to the feeding of young or growing stock. It is a notable fact that milking cows have been known to increase their yield by more than half, when placed on a diet consisting mainly of lucerne, their coats soon assuming that sleek, glossy appearance which denotes good health.

## VARIETIES OF LUCERNE.

Many varieties have been tried by experiment in this country in order to form some conclusion regarding the most suitable types. The list includes Tamworth Broad Leaf, Hunter River, French Provence, Bathurst No. 6, New Zealand Marlborough, Baltic, Siberian, Hansen, Cossack, Semipalatinsk, Grimm's, Montana, Kansas, Peruvian or Hairy Lucerne, Algerian, Arabian, and Turkestan. Tamworth Broad Leaf is a well-known variety which suits the warmer climates and coastal regions where there is a good rainfall, and produces an abundance of fodder. Hunter River and Bathurst No. 6 are both strains of the imported French Provence type, which have been acclimatised in New South Wales, and are giving excellent results. Of the Russian varieties imported, the majority are cold climate Alfalfas, and though good frost resisters, with the exception of Cossack, are poor in leaf and stem. Grimm's, an importation, appears to do particularly well on the tablelands, while Semipalatinsk, which has a spreading habit of growth, is extensively grown in the dry interior of America. China appears to be a promising variety, which, besides stooling well, produces a large amount of leaf. By the foregoing it will be noticed that there is quite a good assortment of varieties from which to make a selection, and a type to suit most localities, though differing widely in their particular conditions.

## CLIMATIC CONDITIONS.

Until recently it was considered that lucerne would only give profitable results on rich alluvial flats, in moderate to warm climates, with moist conditions, either natural or artificially provided, and without doubt these are the ideal conditions or factors contributing to a good stand. To-day, however, there is no question that even in climates formerly regarded as too cold or too dry, good crops can be and are secured, which will yield two or three cuts a season, before turning over to grazing for the remainder of the year. While types which have proved so successful in our recognised lucerne districts are not constitutionally adapted to the colder parts of the Commonwealth, very good results have been obtained in Northern and Midland Tasmania, Gippsland, Western District, and other cooler parts of Victoria, Tamworth, Moree, Griffith, Cowra, and Denman, in New South Wales; in South Australia, chiefly on the Murray Flats; and in Queensland and Western Australia.

## SOIL CONDITIONS AND RAINFALL.

Lucerne, though perennial and so prolific in habit, requires for its successful cultivation certain definite soil conditions, and although it will thrive in a host of soils, and is amenable to wider variations in rainfall than most crops, it needs a deep, permeable, well-drained soil and subsoil in order to establish and extend its efficient root system. Lucerne in fields where damp patches occur will develop wet feet, then it soon dies out and becomes replaced by weeds. It has a great partiality to lime, and granted that it is present in the soil in sufficient quantity, will materially assist lucerne in supplying nitrogen compounds to soils definitely lacking in that respect. This element is extracted from the atmosphere by a complex process, embodying the root nodules and certain soil bacteria, which latter operates best at depths ranging from 12in. to 24in., converting free nitrogen into available plant food. Without making several small experiments, it would be impossible for any farmer to know that lucerne would not grow on his farm or to conclude that it will not suit his particular conditions, when in all probability with only one trial failure may be due to lime deficiency, or poor soil drainage. He should, however, make tests with a number of varieties on different portions of the farm, in order to decide the deepest and best drained soil for the purpose. Lucerne, of course, is dependent on moisture, without which heavy or even good crops are out of the question. A rainfall of 20in. and upwards is desirable, but in good soils where the fall is lower it can be supplemented by irrigation.

Before condemning a district as unsuitable for lucerne culture, farmers should answer the question, "What pasture fodder of a permanent nature will do better." As lucerne makes its maximum growth during the late spring and throughout the summer, frequent falls of rain at that period are distinctly beneficial. This does not imply, however, that in localities where winter rains predominate, lucerne-growing will be unprofitable. The most ideal soils for lucerne are of the rich, alluvial loam variety, found along river banks. The best are of a deep, free nature, abounding in lime and potash, with free moisture at a depth of 15ft. to 30ft. Conditions approaching these exist in parts of New South Wales, chiefly the Hunter River, Tamworth, and Moree districts, where many growers have made comfortable livings on areas not exceeding 30 acres.

#### SOIL PREPARATION.

A good method of preparing soil for lucerne is to grow another leguminous crop, prior to seeding, such as Berseem or Sweet Clover, which may be either grazed or turned under. This has the effect of sweetening the soil, and freeing the land from objectionable weeds, besides which providing humus and available nitrogen for giving the young plants a good start. A reserve of moisture in the soil can then be created by adopting a thorough system of fallowing, which will give the previous cleaning crop sufficient time to decompose. At this stage, while fallowing is in progress, and effort should be made to grade the land and level off the hollows, if required, particularly if the lucerne is to be irrigated. If hollows are allowed to remain, they may prove a harbor for stagnant water, with the result that plants in those patches will become waterlogged, and eventually die out. Where stiff subsoils exist, it may be necessary to use a subsoil plough, for although lucerne is provided with deep penetrating roots, a better stand will usually be secured by this practice. If fallowing has been satisfactorily carried out, however, for at least six months, deeper ploughing than 3in. to 4in. just before sowing is not generally recommended. Working deeper merely buries the sweetened surface soil, destroys the firm condition of the seed-bed, and may promote weed growth.

#### LIMING.

If lime is to be applied, it should be placed on the land in heaps two or three months before sowing commences. After it has thoroughly aired, it should first be partly spread with a shovel, and afterwards evenly distributed by means of the harrow or cultivator during fallowing. Lime should only be worked into the surface, and never ploughed in.

#### THE SEED BED.

The actual preparation of the soil for sowing must be directed towards obtaining a firm seed bed. The most effective treatment for securing this result is by thoroughly harrowing and rolling the land. Except in soils of a light sandy nature, a light harrowing might follow rolling with good effect. If soils are naturally heavy, and inclined to set, it is advisable to break the smooth, rolled surface, in order to avoid excessive consolidation after the first rain.

#### TIME FOR SOWING LUCERNE.

Lucerne may be sown during spring or autumn, this being determined more or less by local climate conditions in relation to climate and weed growth. Generally speaking, autumn sowing is most favored, providing winter conditions are not so severe as to prevent the seedlings from becoming well established. Autumn planting will enable the young plants to thrive without much interference from weeds, and they are therefore better equipped to withstand heat or dry winds the following summer. Spring sown crops, on the other hand, usually have to contend with more vigorous weed growth, besides which they are hardly so well developed before the summer arrives, and in consequence are likely to suffer. In some districts the prevalence of strong winds and dry conditions during spring make satisfactory germination almost impossible, thereby necessitating autumn sowing. Weeds can usually be checked more easily by the summer fallowing preceding autumn sowing, when weeds will be turned up and their roots exposed, before they have an opportunity to seed.

#### QUANTITY OF SEED.

In good lucerne localities the heavier the seeding, within reason, the better; heavy sowing tends to produce crowded plants, thus encouraging the growth of fine stems. Under these conditions 12lb. to 16lb. of seed would not be considered excessive. In drier districts, lacking the advantages of irrigation, lighter sowing of from 4lb. to 5lb., and a space of 9in. to 12in. between plants, will be found advisable, as it permits better standing, and allows for frequent cultivation.

### GOOD QUALITY SEED A NECESSITY.

The quantity of seed required also depends largely on the quality, and on account of the longevity of the crop, it is essential that only the best graded seed is procured. Strangers and other impurities frequently occur in lucerne seed, and include such weed seeds as Fat hen, Wire weed, Docks, Mallows, Ox tongue, Hexam scent, Pigeon grass, Pepper weed, Stink weed, and Dodder. It is quite possible to secure seed over 99 per cent. pure, but should it exceed 5 per cent. impurity, it would be only regarded as second grade, this class also including grains of irregular and shrunken or broken condition, totally unsuitable for successful lucerne growing. Hard seed may cause protracted or uneven germination, but in United States of America a considerable quantity of this sort of seed is processed, by passing through a scarifying machine, whereby the seed covering is scratched and thinned, without detriment to the seed itself. Before purchasing large quantities of this expensive seed, the grower would be well advised to secure several samples. He should first satisfy himself as to the amount of impurity present, and then carry out a few germinating tests, by placing 100 seeds of each lot on separate plates, between a folded sheet of moist blotter. These should be placed in a room where the temperature remains at about 80 degrees, and the paper kept continually moist. If at the end of three days 60 per cent. of the seed has germinated, he can rest assured that it is a good sample.

### METHOD OF SOWING.

Seed may be either drilled or broadcasted, using the grass-seed attachment for the former or the Cahoon, Tiger, or Fiddle for broadcast. If no grass-seed attachment is available, the required amount of seed can be sown by mixing it with a definite quantity of super, and setting the drill to distribute that quantity per acre. A broadcasting effect can be obtained by allowing the tubes to hang free of the hoes, and trailing a strip of netting behind the drill to cover the seed. Preference is usually given to the drilled-in method, on account of securing a more uniform germination, seed economy, and the fact that it facilitates thorough cultivation once the crop is established. Deep seeding usually is not conducive to good results, and care should be exercised when drilling to avoid planting too deeply. The depth to plant should never exceed 1½ in.; usually ½ in. to 1 in. is ample, and rolling after sowing is essential to compact the soil round the seed in order to secure a good stand.

### SUBSEQUENT TREATMENT.

The main object of treatment immediately after sowing, when the young plants are up, is to keep weeds in check, but although light harrowing may be an advantage, it is generally risky at this stage. Probably the wisest method to adopt in retarding early weed growth is to mow the crop a few times, before it commences to flower, at intervals of about three to four weeks. In this way the lucerne plants commence to stool, develop their roots, &c., before weeds have the chance to run to seed. It is advisable not to mow too close to the ground with the earlier cuts, but always leave a few leaves. After the second or third cut, particularly if the ground has set hard, the harrows may be used. The first harrowing should be lightly done, to avoid loosening the immature plants from their position, and only the surface or crust stirred, to admit air, without unduly exposing the roots. After the plants are established, however, and have secured a firm hold, there is little danger of disturbing them even with heavy cultivation or harrowing, except in the case of extremely light-conditioned soils.

### IRRIGATION.

Lucerne is a greedy plant where moisture is concerned, and although good yields are obtained in districts having a rainfall of approximately 20 in., the returns can be greatly augmented by irrigation. Water for irrigation purposes should not be too hard, i.e., the alkali content should be low. It is advisable to allow newly-sown crops to stand for five or six weeks before watering. Irrigate a week before and a week after each cut, if required, but avoid watering when there is practically no foliage to protect the ground. Cultivate again as soon as the land is ready and not too sticky. The amount of water to apply will vary from 1 in. to 4 in., according to the nature of the soil and rainfall. The two best ways of irrigating are the sprinkler method and by flooding, and although the former is a decided improvement on most methods, the plant is fairly costly. Flooding is most commonly practised, and gives very satisfactory results.

### TOP-DRESSING.

Some growers entertain the mistaken idea that, other than the ordinary cultivation given to lucerne, it requires no further treatment. Their argument is possibly due to a limited knowledge of the plant and its habit of growth, and they reason that if lucerne

enriches the soil in nitrogen, and possesses a healthy root system, why should the application of manure be necessary. To be profitable, it requires as much attention as any ordinary crop, particularly on account of its almost permanent nature, and the farmer who desires to prolong its life, and secure the maximum return, will neglect nothing that will tend to invigorate and sustain healthy growth. Experiments conducted in New South Wales prove conclusively that the application of super invariably increases yields up to 200 per cent. over untreated plots in many instances, and in addition to an abundance of healthy green leafage, a better quality lucerne generally is obtained. The most outstanding advantages accruing from the systematic top-dressing of lucerne with super may be summarised as follows:—1. The useful life of the crop may be extended, and unthrifty stands restored to productivity. 2. The yield of fodder is greatly increased. 3. The fodder is generally of much superior quality, and a healthy dark-green growth promoted throughout the growing season.

#### CUTTING LUCERNE IN THE GREEN STAGE.

Lucerne for green fodder should be cut just before it is ready for haymaking, before the flowering stage has progressed too far. It is best, if possible, to wait for a dry day to facilitate mowing and avoid sweating, but if mowing can be successfully carried out, the green stuff may be spread more thinly. This is important when feeding to stock in large quantities, particularly in the case of milch cows, when it is advisable to mow an hour or two prior to using to allow it to wilt slightly. This practice obviates the danger of hoven or bloating, and also, in the case of milking cows, lessens the likelihood of a taint, which commonly occurs with freshly-mown lucerne. For milk production, lucerne in its green state is probably unsurpassed as a fodder, allowing, of course, for the slight objection on account of its tainting properties. Extremely heavy yields of green fodder have been secured, especially under irrigation, and quantities between 5 tons and 6 tons of hay per acre are not exceptional. One distinct advantage it has is that the entire plant is edible. If long enough when cut, it will usually rake up fairly clean.

#### HARVESTING FOR HAY.

This is an operation calling for good judgment and attention to detail. Serious losses are easily involved at this stage due to the shedding of leaf through cutting at the wrong time, or by careless or rough handling. A poor quality hay and light yield is the natural result. Usually a certain amount of flowering is permitted before commencing mowing operations. Generally speaking, after the first few flowers are cut, approximately one-third, cutting should commence, but this will, of course, depend on local conditions, such as the area to be harvested, labor available, and the weather. If cut at the stage indicated, the best quality hay is obtained, and the succeeding growth will be more vigorous. Should weather conditions be hot and dry, the rake should follow the mower closely and cocking be done almost immediately afterwards. For milder conditions allow the crop to remain in windrows several hours. Weather conditions also control the length of time the lucerne remains in the field in cocks. When it is warm and dry, two days should be sufficient, but when mild, cloudy or misty weather is encountered, allow from four to seven days. If remaining for the longer period, it will be necessary to turn the cocks by fork to avoid mould development, which would otherwise seriously injure the quality of hay. The drying out of hay depends more on the condition of the stalks than the leaves, as the former naturally take longer. It requires some experience for the grower to judge the correct time to commence carting in and stacking operations. When the hay is handled it should feel light, soft, and crisp, without being over-brittle. The chief dangers to avoid are:—1. Loss of leaf due to over-drying. 2. Firing in stack through moisture and overheating. 3. Mouldy hay due to being damp when carted in. After a little experience the farmer should be able to avoid these troubles and be able to cure a fair sample of hay.

#### PRESSING IN THE PADDOCK.

Many growers who possess large areas have adopted the method of baling or pressing in the field to save double handling. This practice, to be successful, will depend largely on weather conditions prevailing at harvesting time, and it is essential that they are ideal for the purpose. A push rake may be utilised to bring the hay to the stationary press, and if necessary, cocking can be dispensed with. If it can be done, however, the quality of the hay is greatly improved, curing better, and the plants retain more leaf when properly cocked. The press may be moved from time to time to the centre of a fresh area, thus avoiding long trips with the push rake. Two wires are placed on each bale, which may measure 3ft. 4in. x 1ft. 6in. x 1ft. 4in. Bales when pressed weigh approximately 84lb., and are, therefore, easily handled.

## ADVANTAGES OF PRESSING IN PADDOCK.

1. Simplicity of handling and saving of labor. 2. In only being handled once there is less loss of leaf. 3. The good color in hay is retained by immediately baling. 4. Less space is required for stacking the compressed hay. 5. When carting out a bigger load is more easily put on without waste. 6. If bales become wet, the moisture does not penetrate deeply, and they are easily turned for drying purposes. Quite possibly the grower with a small area under lucerne would hardly be in a position to press it into bales. He would, therefore, find it cheaper and more convenient to stack it, but for preference this should be done under cover if possible.

## NUTRITIVE VALUE OF LUCERNE HAY.

Of all the legume hays, lucerne takes the foremost position, on account of its higher content of crude and digestible protein and lime. American experiments conducted during 1927 showed that Alfalfa (Lucerne) produced an average of 2.79 tons, Clover 1.75 tons, and Timothy Grass hay 1.28 tons per acre. The total yields of crude and digestible protein were:—Lucerne 591lbs., Clover 266lbs., and Timothy Hay 86lbs. per acre. Lime contents were:—Lucerne 108.8lbs., Clover 56lbs., Timothy 7.15lbs. In Lucerne, the total digestible nutrients were 2,879lbs., Clover 7,781lbs., and Timothy 1,387lbs. per acre. The American experiments in this connection go even further, and the estimated cost of 100lbs. of crude and digestible protein is as follows:—Alfalfa, 12.02 dollars per ton=5.66 dollars per 100lbs. protein; Clover, 11.91 dollars per ton=7.83 dollars per 100lbs. protein; Timothy, 11.31 dollars per ton=18.85 dollars per 100lbs. protein. From a comparison of the foregoing figures it would take 3.5 tons of Timothy hay, at a cost of 39.58 dollars, to produce the protein equivalent of 1 ton of Alfalfa hay, costing only 11 dollars. Even when compared with high protein concentrates such as linseed or cottonseed meal, lucerne compares more than favorably in cost per 100lbs. protein at average market rates. If dairymen in particular, and stockowners generally, would produce and feed more protein in the form of legume hays, their feed bills would be considerably reduced, and they would have an admirable basis for securing an economic, properly-balanced ration. In addition to supplying more milk-making nutrients at a much lower cost, legumes are far superior to non-legumes in palatability. They are also superior in the lime content and quality of the protein. The essential amino acids present in legume hay also supplement to advantage that particular deficiency in cereal hay or silage. All clovers make good hay when cut at the proper stage, and well cured, but most dairymen consider that it is hardly equal to lucerne hay, though a close second.

## FEEDING TRIALS.

Experimental feeding trials comparing legume hays with non-legumes for milk production have invariably shown that the former produce more milk at lower feed cost. Not only are legumes efficient in this way, but they are almost indispensable for the correct feeding of dairy heifers. Their palatability and high content of necessary bone and flesh-forming nutrients commend them for inclusion in the ration of growing animals.

## LUCERNE SILAGE.

Although lucerne by itself is not generally recommended for ensilage, there are quite a number of farmers on the Murray irrigated flats who have utilised it in this way with success. It needs more care and judgment to decide just when the crop is fit, and a great danger of spoiling the entire crop through scouring and fire. When mixed with cereals, maize, or sorghum, it forms a rich, sweet, succulent fodder which is probably unequalled for feeding to milk cows. The crop should be cut a little earlier than when intended for hay and immediately carted into the silo. In this way practically the whole green weight of the fodder is retained. As a rule, when cured on its own, it makes a heavy dark silage which, however, is usually greatly appreciated by stock.

## LOCAL RESULTS WITH LUCERNE.

We have a very fine example of lucerne under irrigation at Kybybolite Experimental Farm. The area comprises two sections of 1.62 acres and 3.15 acres respectively, the former being sown down in 1923 and the latter one year later. The usual practice is to cut the majority green for cattle feed, the last cut, however, being utilised for hay. Approximately six waterings are given during the drier months of the year. During the season 1926-1927 28.36 acre inches were applied in this way. The smaller section was top-dressed with 15 tons of farmyard manure per acre immediately after the hay cut in November, then dressed with 2cwt. of 45 per cent. superphosphate the following January.

*Harvest Results of Lucerne.*

|                               | Tons. Cwts. Lbs. |    |     |                       |
|-------------------------------|------------------|----|-----|-----------------------|
| 1st season . . . . .          | 8                | 19 | 87  | green weight per acre |
| 2nd season . . . . .          | 22               | 2  | 32  | green weight per acre |
| 3rd season . . . . .          | 22               | 0  | 109 | green weight per acre |
| 4th season (5cwts.) . . . . . | 18               | 1  | 73  | green weight per acre |

The second section is conducted purely on experimental lines to discover and compare the effects of different phosphatic fertilisers, and for this purpose is divided into six separate plots. Results so far favor plots 1 and 2, the former dressed with 1 ton lime in 1924 and 6cwts. 45 per cent. super 1925-1927, the latter with 6cwts. 45 per cent. super during 1925, 1926, and 1927. The remaining four plots dressed with less soluble forms of phosphates neither yield nor look as well as the first two plots. Mr. C. T. Major, of Glenburnie, has a total area of 12 acres under lucerne which is not irrigated. This is sown on light sandy soil, which if cultivated in windy weather, drifts badly. Mr. Major contends that the planting of lucerne on this portion has, to a large extent, prevented serious drifting. He has now taken off 64 cuts—an average of four cuts annually for 16 years off one sowing. During August the crop is cultivated twice with a spring-tooth, then dressed with 1cwt. of super, and finally harrowed. The first cut, usually ready before Christmas, is utilised for hay, and has frequently attained a height of 3ft. with good stooling. Unfortunately, no record has been kept in connection with yields. Usually a bright warm day is selected if possible for harvesting. The crop is cut, raked, and cocked all in one day. Following the hay-cut there are usually three more for green feed at approximately one month intervals. Another local grower is Mr. R. R. Mackay (The Springs), who has a large portion of his farm sown down with lucerne. This is the principal fodder used on the farm, chiefly for dairy cows, both as hay and in the green state. Some of the paddocks (none of which are irrigated) have been established for the past 20 years, and some very fine crops have been harvested. Mr. S. J. Bonney, of Glencoe, is another who has had success with the cultivation of lucerne. In addition, there are several more small plots to be noticed around the district that appear to be giving very favorable results. It would appear from the foregoing that lucerne should suit this district very well. Provided proper care in soil preparation is observed, and a good sample of seed secured, it should not prove a difficult crop to establish. Although the lucerne flea is a rather troublesome pest in this district, the period of its destructiveness is usually fairly limited, and during some years it is hardly seen at all. In normal seasons allowing for its depredations, the grower should secure at least four, possibly five, cuts per annum off an established crop in the South-East.

**UPPER-NORTH DISTRICT.****(PETERBOROUGH AND NORTHWARD.)**

MORCHARD (Average annual rainfall, 13.58in.).

August 15th.—Present: Seven members.

**FARMING COSTS.**—Mr. B. McCallum read the following paper:—"Any person contemplating farming must carefully consider land values, and it must be admitted that the prices paid in the past decade for agricultural land have been above productive values. In this district—mostly outside of Goyder's line of rainfall—farms have been sold at £7 per acre. This outlay, on present prices of farm produce, is not likely to return interest after working expenses are accounted for. The same applies in good rainfall districts. The large sum of money required to purchase land on which to commence farming must make farming expensive in the settled districts. Take a 700-acre holding at £10 an acre—and one could not purchase inside of Goyder's line a moderately improved farm for less than that figure—interest alone on that holding would be £455 at 6½ per cent. This means that the holding must yield big averages to make farming pay. The question is often asked, 'what is the cost to the farmer to produce a bushel of wheat?' " The speaker then quoted figures of costs of production from a paper, in the May issue of the *Journal of Agriculture*, by a member of the Alma Branch. "Such costs to the man on the land, owing to the fact that he cannot pass them on, and the expenses which are continually being forced upon him by the ever increasing cost of production, is one of the biggest of the many problems which confront the primary producer. Nearly all other classes of the community receive Government protection in some way or other, and can also pass their additional expenses on by adding to the price of their manufactured articles, and through organised concerns this is easily done. There are only two ways by which the farmer can expect to get any relief—

first, by securing a greater yield per acre for the same cost of working per acre; and secondly, to eliminate waste and turn it to profit. In dealing with the costs of working per acre one must have a thorough knowledge of the most economic method of tilling the farm in his own particular locality. Increased yields may be brought about by improved varieties of wheat, selected varieties for certain classes of land, and taking advantage of the late, mid, and early wheats, according to time of seeding. To eliminate waste which takes place through the purchase of unsuitable machinery on many farms; implements that are dear to purchase have been used but a few seasons and then put aside, and something else purchased to take their place. Then light implements should not be expected to do a heavy implement's work. Each implement should receive proper adjustment and be protected from the weather when not in use. Waste also takes place on many farms through overfeeding farm stock. When plenty of feed is available a suitable ration should always be supplied, and when the opportunity comes for storing fodder, it should be taken advantage of, especially in the dry areas." (Secretary, Mr. A. McCallum.)

#### WEPOWIE.

Meeting held August 19th at the residence of Mr. Gregurke. Present: 11 members and 85 visitors. Mr. E. L. Orchard (District Agricultural Instructor) gave an address, "The History of Bread-making." The meeting then took the form of a social evening. (Secretary, Mr. E. Rooke.)

### MIDDLE-NORTH DISTRICT.

#### (PETERBOROUGH TO FARRELL'S FLAT.)

BELALIE NORTH (Average annual rainfall, 17.95in.).

August 4th.—Present: Nine members.

**FARM MANAGEMENT.**—Mr. A. Bray read the following paper:—"To manage a farm in a business-like manner, the farmer should adopt as his motto 'A place for everything and everything in its place,' and he will be saved endless time and worry. First, have the homestead situated as centrally as possible, so that time occupied in going to and returning from work will be reduced to a minimum. Have a blacksmith's shop, and equip it with the necessary tools and a good assortment of nails, bolts, screws, washers, etc. Keep a few well-seasoned posts on hand, also a good wire strainer for effecting repairs which become necessary from time to time. Convenient gates that are easily opened and large openings in fences through which one can take the widest implement without dismantling will prove the means of saving much time. Now that the motor car is so universally used, the farm will not be complete unless a motor ramp is provided. Plenty of shed room for implements will prove a good investment. After a machine has finished its work for the season, take a note of any parts that are worn out or broken, and order them just prior to the next occasion on which the machine will be needed. Provide the horses with warm and comfortable quarters, and place the chaff shed in such a position that it will facilitate feeding. If a tractor is used, see that it is overhauled before the busy seasons commence. On most farms a flock of sheep is a necessity. Sheep assist in the cultivation of the land, and supply the homestead with meat. Fowls, cows, and pigs are also worthy of consideration. A diary in which is recorded the history of the various paddocks, livestock, &c., will prove most valuable, and in later years made interesting reading. Pay as many accounts as possible by cheque. The heels are of considerable assistance in compiling income tax returns." Discussing the paper, Mr. Carmichael thought farmers should take more care in keeping a set of books of the various farm transactions. For the moving of implements from one part of the farm to another Mr. Bray suggested a race. (Secretary, Mr. E. Carmichael, Jamestown.)

BELALIE WOMEN'S (Average annual rainfall, 17.95in.).

July 8th.—Present: 23 members.

**THE DEVELOPMENT OF INFANT TRAINING TO THE PRESENT TIME.**—Mrs. Moy read the following paper:—"Education, in the sense of preparation for life, must be as old as mankind, because the continuity of the human race would have been impossible if father and mother had not taught son and daughter how to provide the necessities of life. Each individual family in the earliest days received its education at home, but soon after the discovery of the art of writing, with its essential complement, the art of reading, the advantage of collective instruction by specially qualified persons must have soon become apparent. Schools being co-eval with civilisation, it seems rather remarkable that the idea of sending infants to school should be so very modern. Still, when we realise how precious the little one is to its mother, we can imagine how grudgingly

she hands over her care. Mothers must be convinced that the teacher is a competent, lovable, and understanding person, who will deal wisely and gently with her child. In the year 1769 a man who took great interest in infants was discovered in the name of Frederick Oberlin; he also had met a lady named Sarah Banzel, whom he appointed as a conductress of early youth. So much did this lady do for the betterment of Infant Schools that "The Medal of Honor" was conferred on her by the French people. The little ones were assembled in airy, spacious rooms and watched closely. Amusement played a great part in the scheme. The children were taken for long walks by the teachers and made to find flowers which had been described to them. About 1800, a managing director of a spinning mill began a series of industrial and social development. In order to make the cotton industry pay, children were required to go to work at the ages of 6, 7, and 8 years respectively. The famous Frederick Oberlin, who had done so much in reforming children's life, advised parents to keep their children at school until they were 10 years old. There they were taught reading and writing from 5 years to 10 years. About this time Oberlin had a large playground and building erected. The children were admitted at the age of 3 years, and were constantly superintended to prevent the infants acquiring any bad habits, also to form their dispositions and to mutual kindness towards each other. No punishments were allowed in Oberlin and Sarah Benzel's school. The importance of training the mind young was stressed when the children were allowed to enter at 3 years. There were no books, children were taught by common objects. About this time some infant teachers reverted to the rod, consequently they lost favor. A great philosopher named Frederick Froebel seems to have understood the child much more intimately than most men. He says: 'We grant space and time to young plants and animals, so that they will grow properly and develop well. Infants are incapable of receiving instruction given to older children. When children play together (that is, without older people watching) they sharpen each other effectively. For the one does not surpass the other in depth of invention, and there is among them no assumption of superiority one over the other, only love, candor, and free questionings and answers. All parents know that the elder child does not learn as quickly as the succeeding ones. Training children is vastly different from teaching them. Froebels' kindergartens, or 'Children's Gardens,' were beginning to flourish. The teacher was the centre of attraction and was always in the limelight. She was to be bright, sympathetic, attractive in her dress, and the children liked to hear her talk. The present day kindergarten provides small chairs and tables, play aprons, little buckets and spades. This all lends an air of development to the children's minds. During Froebel's time came a marvel of the age in the person of Dr. Marie Montessori. Students came from all over the world to see her methods and attend her training schools. Her schools were called Bambini, and were situated in the poorer quarters of the city in Italy. She was a medical doctor, and Dr. Seguin gave her the advantage of his treatment of mentally defectives. She improved on his methods by providing material for these children to such an extent that these subnormal children were able to pass the ordinary school examination. Having succeeded so far, the idea came to her that she might do the same with ordinary normal children, though younger. The Montessori teaches, observes, directs, but in such a quiet manner that one does not notice her in the room. The children are so intent on their work that they pay no attention to anyone coming or going. The Montessori school gives the greatest freedom to the child. Each child recognises that the other child's interests are as important as his own. He marches to music, is told stories, sings the nursery rhymes, has a swing or a see-saw, and not a word about lessons. He learns his reading sounds by sense, touching sandpaper letters, over and over again. Everything which can be taught by touch and the senses is done. In conclusion, if our great grandfathers were to re-visit the scenes of long ago, they would be amazed at the rushing through the air at incredible speed, at telephone wires and thousands of wonders of electricity. All these have been accomplished by observing the laws of nature and studying them. Now the great advances which have been made in child study are no greater than these things, which can be brought about by honestly and sincerely studying the ways of the little ones. That is the essence of present infant training.'

CALTOWIE (Average annual rainfall, 16.94in.).

Meeting held August 18th. Present: 28 members. Addresses on the subject, "The Value of Crop Competitions," were delivered by Messrs. E. L. Orchard (District Instructor) and A. J. Symonds. Mr. R. Wilkinson offered a trophy for the crop competition which the Branch decided to hold. (Secretary, Mr. R. Wilkinson.)

#### EVERARD EAST.

August 6th.—Present: 12 members and visitors.

Mr. C. Hughes read a paper, "Which is the Best Breed of Fowl for the Farm." He favored the Barred Rock, because they were fair layers, good table birds, and did not fly on to sheds and haystacks. Mr. Hentschke recommended Black Orpington hens crossed

with a Minorca cock. General opinion was in favor of Black Orpingtons. Mr. G. Reinke then read a short paper, "How Long Does it Take Wheat to Malt?" After digging up seed he was of the opinion that it took from 10 to 14 days to malt. Where seed was only just covered it was quite sound and good, but any grain sown deep had grown, and when sown at medium depth perished. Mr. Colton said where he had sown deep the crop had come up, one float of his combine had become strained and did not go in as deeply as the rest, that strip had only half come up. Other members said that deep sowing had grown better this year, but most seasons shallow sowing seemed to be best. (Secretary, Mr. F. Hughes, Blyth.)

**GLADSTONE** (Average annual rainfall, 16.44in.).

August 22nd.

**THE SALE OF FARM-GROWN PRODUCE.**—Mr. J. Gale read the following paper:—"Most of the products grown on the farm have to be sold to buyers who decide the price they will pay and the farmer has to take the price that is offered. The farmers in South Australia are most up to date in their methods of farming, with the result that they get a large yield at the least possible cost per acre. We have Agricultural

**KYBYBOLITE EXPERIMENTAL FARM.**

Farmers' Day, November 18th, 1930. Baling Clover Hay.

Bureaus, Agricultural Shows, Crop Competitions, Fallow Competitions, Better Farming Trains, helping us to co-operate to grow larger and better crops, but when the crop is ready for market, each farmer offers his wheat separately in small quantities. The farmer does not take sufficient interest in the financial side of his business. The unionist has secured a uniform wage, and one cannot get a man below the basic wage, or a worker in the shearing-shed or factory without his union ticket. If the primary producers of Australia were united we would enjoy much better conditions than we do to-day. All other classes in the community, whether labor or capital, are organised, and use their weight in their own particular interest, which is often to our disadvantage financially. The primary producer should unite as he does in the Bureau to improve his method of production, to improve the marketing and financial side of his farm. If the producers of Australia were properly organised, they could have their own representatives watching their interests at home and overseas. The marketing of products such as barley, oats, skins, meat, butter, eggs, and dried fruit could be improved by the better organisation of the producer. The prices for farm products have fallen very low, and the only way to make the farm profitable is to reduce production costs, and, if possible, increase yields per acre." The paper provoked a keen discussion. (Secretary, Mr. F. Chick.)

**JAMESTOWN** (Average annual rainfall, 17.95in.).

Meeting held June 29th. Present: 15 members. Mr. J. O. Hatter (District Dairy Instructor) delivered an address, "Animal Nutrition."

On July 29th Professor A. J. Perkins, Director of Agriculture, delivered an address, illustrated with lantern slides, "The World's Position of Wheat." Twenty-two members and 40 visitors attended.

Fourteen members attended the meeting held on August 25th, when the following papers were read and discussed:—"Vegetable Gardening," Mr. W. Symonds, and "Care and Management of Agricultural Machinery," Mr. G. Napper. (Secretary, Mr. A. Bowness.)

#### MOUNT BRYAN (Average annual rainfall, 16.87in.).

Meeting held August 9th. Present: Mr. G. Goodridge (Chair) and eight members. An interesting paper, "Rural Conditions in England," was presented by Mr. T. Lloyd. (Secretary, Mr. H. Edwards.)

#### MURRAYTOWN.

Meeting held March 8th. Present: Nine members and three visitors. Mr. T. Drummond read a paper, "The Sunshine Header." (Secretary, Mr. E. B. Pitman.)

#### NELSHABY WOMEN'S.

August 7th.—Present: 15 members and visitors.

The Secretary read a paper, "Hints on Jam Making," given by Mrs. E. McCall at the Annual Congress last year. The paper was freely discussed, but members were of opinion that home-made jams and preserves were less expensive than buying the ready-made goods. Mr. K. Nolan read a paper on "The Flower Garden. The Secretary contributed a paper on the "Art of Dressing." (Secretary, Miss A. Lawrie.)

#### REDHILL (Average annual rainfall, 17.02in.).

August 5th.—Present: 12 members and visitors.

PREPARATIONS FOR DROUGHTS.—Mr. L. Simmonds read the following paper:—"In a lesser or greater degree, droughts affect every industry, and are the controlling factor in the law of supply and demand. The possibility of drought causes preparations to be made to guard against them in many ways. By fallowing, the farmer assists the soil to retain moisture which is the controlling factor of successful agriculture in a dry country. Also, fertilisers and new varieties of wheat help to reduce the effects of drought. The dry year of 1914 cost the settlers in new districts and the Government thousands of pounds, and the last three years have been a repetition of that experience. If farming had been carried on in the good years with the fear of a drought being experienced the next year, better provision for fodder supplies could have been made. Fallow well and early, and conserve all fodder available in good seasons. Cocky chaff mixed with oats makes an excellent food, and horses work well on it. If properly covered with straw cocky chaff will keep for years and prove a valuable asset in times of drought. A few stacks of straw are of a great value, and if salt is sprinkled occasionally over the straw as it is being stacked, its palatability will be increased. Whenever possible, every farmer should store more hay than will be fed in the year immediately succeeding the harvest in which the hay is cut. Try and conserve a supply which will last over two years. Saving oats and barley in good years is a suggestion well worth the consideration of every farmer. Most farmers on newly settled land are not in a position to store fodder, but the lessons of the last three years should teach every producer the advantage of preparing for drought." (Secretary, Mr. S. Pengilly.)

#### YANDIAH.

On the occasion of the Annual Meeting, the Secretary read the annual report and balance-sheet, officers were elected, and a programme of meetings arranged for the next session. (Secretary, Mr. F. Jettner.)

### LOWER-NORTH DISTRICT.

#### (ADELAIDE TO FARRELL'S FLAT.)

AUBURN WOMEN'S (Average annual rainfall, 24.12in.).

August 19th.—Present: 12 members and four visitors.

POULTRY KEEPING.—The meeting was held at Mrs. Kelly's residence. Members inspected the poultry pens. In discussing the management of the birds, Mrs. Kelly said the pens should face the north or north-east. She advised the provision of plenty of scratching litter in the pens to keep down the condition of the birds. The birds were fed on wheat, and at midday they were given finely chopped green feed. Mash was fed every other morning and plenty of shell grit and fresh water were always available. Mrs. Kelly made a practice of not keeping the birds after they were two years old. The incubators and brooders were also inspected. The chicks were fed on rolled oats and

No. 1 chick food, with warm water to drink. After they were three weeks old No. 2 chick food was given and the chicks were allowed the run of the scratching pen. (Secretary, Mrs. B. Burfield.)

On August 15th Miss E. Campbell, of the Education Department, gave an address, "Home Economics." There was an excellent attendance, including members from the Saddleworth and Wirrulla Women's Branches.

#### HANSON.

An excellent meeting was held on August 4th. The meeting took the form of a debate, the subject being, "Is the land in this district too dear?" Speakers debating the affirmative were Messrs. C. Turner, J. Hogan, W. Woollacott, and H. Schumacher, whilst the negative was supported by the following members from Black Springs:—Messrs. C. Heinrich, H. Rodda, R. Turner, and J. Howard. Black Springs won the debate by eight points, totals being—affirmative, 347; negative, 355. The Rev. Lawson, of Koorunga, adjudicated the debate. (Secretary, Mr. J. Boehm.)

#### LIGHT'S PASS.

The meeting held on August 4th was attended by 40 members and visitors. Papers on price fixing were read by Messrs. C. Verral and N. Mader. An interesting debate followed, the general opinion being that so long as prices fixed were reasonable and growers stood firm to their agreements and did not under sell, there would be beneficial results. (Secretary, Mr. C. Verral.)

#### MUNDALLA AGRICULTURAL BUREAU.

Field Day, November 12th, 1930. Visitors inspecting Subterranean Clover and Grass Pasture.

#### MODBURY.

The monthly meeting of the Branch was held at Golden Grove on August 6th, there being present 11 members and six visitors. An address, "Fodder Crops and Their Cultivation," was delivered by Mr. W. J. Spafford (Deputy Director of Agriculture). (Secretary, Mr. M. Murphy.)

#### OWEN.

August 6th.—Present: 15 members and 100 visitors.

Annual Meeting.—The annual social in connection with the activities of the local Branch was held in the institute on August 6th. The Chairman of the Advisory Board (Mr. F. Coleman) addressed a large gathering of members and visitors on the subject, "How to Use Your Bureau." He stressed the importance of farmers utilising their sidelines, particularly dairying, in view of the depression of the wheat market and the annual shortage of dairy produce in South Australia. Mr. W. Johnson (District Agricultural Instructor) and Mr. W. Brownrigg (Agricultural Instructor for Eyre Peninsula) were also present. The retiring Secretary (Mr. A. N. Freebairn) gave a report on the Bureau's activities for the past year. Prizes won in connection with the Balaklava District Wheat Crop Competition were presented by Mr. F. Coleman, the successful competitors being, first, Mr. J. Harkness; second, Mr. W. McPharlin; third, Mr. B. Reid. Representatives from the Alma, Balaklava, and Nantawarra Bureau Branches were present. A musical and elocutionary programme was provided. Supper was served by the ladies, after which the evening concluded with a dance. (Secretary, Mr. A. Bowyer.)

## PENWORTHAM.

The meeting of August 7th was held at Seven Hills, and was attended by 25 members and a large number of visitors, including members from the Clare and Watervale Branches. Addresses were delivered by Messrs. W. J. Spafford and W. C. Johnston, of the Department of Agriculture. (Secretary, Mr. A. Jenner.)

## RIVERTON (Average annual rainfall, 20.86in.).

Mr. D. Hannaford presided over an attendance of 27 members and 134 visitors at the meeting held on August 11th, when Mr. B. Crewe, of the Vacuum Oil Co., gave an address, illustrated with moving pictures, "Oil and Its Products." (Secretary, Mr. O. Longbottom.)

## SADDLEWORTH (Average annual rainfall, 19.65in.).

Eleven members and visitors attended the meeting held on August 8th, when an instructive paper, "Sport and Recreation in Conjunction with Farming" was contributed by the Secretary, Mr. A. Blundell.

## TARLEE (Average annual rainfall, 18.16in.).

Meeting held July 8th. Present: 15 members and two visitors. Papers on the subject, "Systems of Marketing Wheat," were contributed by Messrs. G. Cornish and L. M. Molineux.

Sixteen members attended the meeting held on July 29th, when Messrs. A. Hill and N. Clarke read papers, "Farm Side Lines."

A further meeting was held on August 19th, when W. C. Johnson (District Agricultural Instructor) delivered an address, "Weeds and Grasses." (Secretary, Mr. D. Kelly, Giles Corner.)

## TRURO (Average annual rainfall, 20.21in.).

August 11th.—Present: 24 members.

DAIRYING AS A FARM SIDE LINE.—The following paper was contributed by Mr. J. Miller:—"Dairying as a side line on the farm is not only a payable proposition, but a necessity, inasmuch as it provides three of the valuable foods of life in milk, cream, and butter. The fortnightly cream cheques are also a great help in the home in making ends meet. In the skim milk we have a food which is unequalled in the raising of young pigs. The number of cows which a farmer should keep will depend largely upon the size of his holding and the help of his family. I would suggest for an average farmer the keeping of five cows, and an attempt should be made to keep four in milk. The cows should be milked regularly, thoroughly, and quickly. For the most suitable breed of cattle I favor the milking Shorthorn. This type of animal, when it has served its purpose as a milker, can be fattened and sold to the butcher at a good figure. There is also a better demand for a good Shorthorn calf than for those of most other breeds. During that part of the season when feed in the paddocks is scarce cows should be fed twice daily on chaffed hay and crushed oats (cocky chaff in drought years only). Every farmer should endeavor to grow all the fodder, otherwise the keeping of any kind of stock will not be profitable. Some farmers will feed a useless horse on hay, yet expect the cows to maintain their condition and produce milk on cocky chaff with a very small allowance of bran. A cow should be fattened and sold to the butcher after she attains the age of 12 years. If possible, a small paddock should be reserved for the cows close to the homestead so that time will be saved by having the cows handy at milking time. A cow should be given at least six weeks rest before calving, and two weeks prior to that six weeks should be allowed for drying off. I do not favor a cow having a calf more often than every 18 months. A heifer should be at least three years old before she has her first calf; if the heifer is allowed to get in calf when too young her growth will be very much checked. Great care should be taken with the milking of the heifer, there are many good cows spoiled by neglect during their early life. Such troubles as blind teats, calloused udders, &c., develop from neglect. The young calf should be given new milk for at least the first 14 days of its life, and then gradually weaned on to separated milk with a little Meggitt's meal added, and fed until it is three months old, when it can be turned out, providing there is good feed in the paddock. If a calf is intended for market, then very often it pays to sell before they are three months old. A young calf will often learn to drink much easier if given its own mother's milk for the first few drinks. If a heifer calf is to be reared, it should be handled quietly at periods during its young life, so that when it has its first calf little trouble will be needed in getting it to stand quietly to be milked. I do not favor leg-roping cows, the rope only makes them kick more, and if cows get at all upset they will not give their milk freely." (Secretary, Mr. L. Davis.)

## WASLEYS.

Mr. E. Fischer presided over an attendance of 40 members at the meeting held on August 14th, when Mr. F. Gilbert, lecturer on Poultry at the Roseworthy Agricultural College, gave an address, illustrated with lantern slides. In the course of the address he emphasised the necessity of producing the infertile egg, as was essential for export purposes. He advised selecting the best hens and male birds for breeding. The good hens could be judged by their heads. If hens and cock birds were allowed their freedom together often the hens stole their nests and hatched chicks of an inferior nature, similar to herself, as would be a spring layer, which is not to be recommended, as it is a poor hen that isn't laying during spring. The younger birds should not be allowed to feed with the older birds. Select the best birds after six weeks and concentrate on them. Change of fodders was necessary. The morning feed should be an easily digestible one, such as bran and pollard mash, green feed at midday; barley and oats could be fed as a change, but fowls should not be kept on these grains for any length of time, as they caused digestive trouble; malt barley was preferable to Cape barley. If birds were moused they should be supplied with meat food, also shell grit should be given, as 137lbs. of carbonate of lime was utilised by 100 fowls producing 100 eggs annually. Care must be taken of eggs for incubation purposes, and if kept for any length of time prior to being placed in the incubator, should be covered, to prevent moisture evaporation. After eggs are placed in the incubator, two days should elapse before being turned. The airing should be increased as the hatch progresses. The chicks should be separated as soon as the sexes can be determined. (Secretary, Mr. C. Currie.)

## WATERVALE (Average annual rainfall, 27.24in.).

June 16th.—Present; 27 members.

CULTIVATION IN RELATION TO VINEYARDS, DEALING PRINCIPALLY WITH CONSERVATION OF MOISTURE.—Mr. T. Sobels read the following paper:—"Vines that are cultivated require cultivation for a variety of reasons, the main reason being that they are placed under natural conditions, consequently they have a keener struggle for existence. In a dry country, one of the chief difficulties is the absorption of a sufficient quantity of moisture. We are told that average plants will contain from 70 per cent. to 80 per cent. of water. Moisture is constantly evaporating through the leaves, and this loss has to be made up by other absorption. It is estimated that to produce one ton of hay it requires approximately 250 tons of water, and 1 in. of rain represents 100 tons to the acre. Therefore, if no losses were to occur and the rain fell as required, a rainfall of about 2½ in. would be sufficient. Only about one-quarter of the rainfall is used by the plants, fully one-half is lost by evaporation, and the rest soaks away. Therefore our main object is to prevent as much of this evaporation as possible. So far as cultivation is concerned, it may be divided into two parts. Firstly, the storage in the soil of as much moisture as the rainfall will allow, and secondly, the prevention of the loss of this moisture as far as possible until the succeeding rainy season. At the end of autumn the soil has become more or less consolidated. Every operation after the bursting of the buds naturally tends to increase this. Summer cultivation is shallow, simply a stirring of the surface, leaving it hard and solid below. Even sandy soils, as a rule, contain a certain per cent. of clay, tending to set them on the surface. As soon as the rain falls in winter, the surface being hard, the greater percentage of water simply runs away, particularly on slopes, and even if level the water collects on the surface and much again evaporates without going any depth. If, however, the soil is broken up to get below the summer cultivation, the greater part of it soaks into the soil. Therefore I would advise the breaking up of a vineyard as early as possible, according, of course, to the district and rainfall. There is no doubt, however, that whatever precaution is taken the moisture that is in the soil must diminish. Firstly, by evaporation, owing to rise in temperature as the summer advances; secondly, by the action of violent winds; thirdly, by the gradual heating of the soil by the direct rays of the sun; and fourthly, robbing of moisture by weeds and any other foreign growth. The latter, of course, we are able to deal with. The action of cultivation is not confined entirely to the storing of moisture, by the cultivation of the soil we force the plants to send their roots down deeper than they otherwise would do. Plants require an abundant supply of free oxygen, and soils which are not cultivated become rich in carbon di-oxide, owing to the respiration of root gases. Scientists have told us that 10 per cent. of carbon di-oxide is contained in pasture land. This tends to cripple the plants and hinders their growth, hence breaking up of the soil exposes their lower layers and sets free the poisonous gas. Cultivation may be divided into three stages, viz., winter, spring, and summer. The winter cultivation is given as early as possible after the ground becomes ploughable, and is only necessary to the dryer districts. Spring ploughing is mostly practised here, and should be of a good depth, varying from

4in. to 6in. In trellised vines the crown should be made in the centre of the rows, throwing the furrow away from the vines, plough as closely to the vines as possible, then the remaining land is taken away by the horse hoe. Later on this should be ploughed back, leaving a furrow in the centre of the rows, which is worked over by the use of the harrows and cultivator. In bush vines in this district only one ploughing has been found necessary, and that is to strike out or crown up one row, leaving the furrow on the next, the remaining land being taken away by the horse hoe. Each row is done every alternate year in this manner; one row is backed up and the other ploughed away, and so on. Before summer cultivation I recommend the use of the harrow. This not only pulverises the surface, but assists the cultivator to do the work more thoroughly and lessens the wear and tear of implements. The number of times you cultivate in summer depends chiefly on weeds and the season. Loosen up the soil after every rain where practical, to prevent as much evaporation as possible. Summer cultivation places a loose layer on the surface, which sometimes encourages the growth of surface roots, but the deep winter or spring ploughing tends to destroy these, so the deeper one can force the roots of a vine down the better will they withstand droughty conditions, the small surface roots being of no value. In an uncultivated soil much loss is due to capillarity. When a soil sets hard it forms a crust on the surface, and although the particles tend to cohere, you never obtain a perfectly compact mass. The soil is really perforated with a series of minute tubes connecting the lower strata of the soil with the atmosphere, and through these tubes the moisture is constantly rising and is lost by evaporation from the surface. Breaking up the surface remedies this, and practically the only loss will then be by evaporation from the surface layers. Shallow cultivation in the summer, leaving a lower layer on the surface, acts in much the same way as a mulch."

#### WILLIAMSTOWN WOMEN'S (Average annual rainfall, 27.84in.).

Mrs. Rowe presided over an attendance of 10 members at the meeting held on August 6th. Mrs. Hill tabled recipes and samples of marmalade and pickles. Mrs. Wild gave a demonstration of root grafting. (Secretary, Mrs. C. Cundy.)

### YORKE PENINSULA DISTRICT.

#### (TO BUTE.)

#### ARTHURTON (Average annual rainfall 16in. to 17in.).

The meeting of August 4th was held at the residence of Mr. L. Lamshed. Mr. J. Hentschke presided over an attendance of 21 members and five visitors. An address, "Improving the Farm Flock," was delivered by Mr. W. J. Spafford (Deputy Director of Agriculture). (Secretary, Mr. T. Howlett, Moonta.)

#### BRENTWOOD (Average annual rainfall, 15.67in.).

August 7th.—Present: 14 members and three visitors.

**PIGRAISING FOR THE FARMER.**—Mr. C. Boundy contributed the following paper:—"For breeding purposes I prefer the Old Spot mother, the sows are very quiet and rear large litters, and crossed with the Duroc-Jersey boar produce quick growing pigs, which develop a good side of bacon. Pig grazing has many advantages over sty and yard rearing. Properly carried out it is more profitable and far less laborious than intensive hand feeding. From the time it is born the sucker learns to root and fossick for itself, and thus naturally becomes hardy, healthy, and less susceptible to swine fever; and the mother will, as a rule, throw bigger litters and rear more of the youngsters than when confined in small spaces for a long time. It is advisable, however, to move the sow into a sty, with a protective beam 5in. from the ground, a few days before farrowing, and leave her there for about a week after the young are born. This ensures protection from possible bad weather and from interference by other pigs during farrowing. If this is done, care should be taken not to change the diet too suddenly and not to overfeed. Pigs will put on weight more quickly when fossicking in good pasture, such as lucerne or Cape barley, but growing or fattening pigs, especially the latter, should be given an additional grain ration of, say, crushed oats, wheat, barley, or peas; charcoal and old bones should also be fed. All grain food should be crushed; feeding whole grain is wasteful; and a plentiful supply of fresh water should always be available, whether in yards or pasture. Shelter-sheds should be provided in the paddocks, and shady trees are almost an essential in hot weather. Where pigs are grazed, greater numbers can be raised with the same manpower than when in confined quarters. Feeding costs are greatly reduced, the bacon or pork will be firmer with more tendency to streak, the necessity for milk is eliminated, though

milk is always a valuable food, and the stock, when fit for market, can stand the journey without hardship. As live weight increases the greater the quantity of feed required to maintain the pig at his existing weight. Five pounds of corn, or its equivalent, will produce a pound of gain in a young pig; it will take nearly that to keep a 200lb. pig at the poundage; the younger they are when they reach the 120lb. (dressed) weight the more profitable. A pig that is putting on 1½lbs. per day is showing more profit per pound of feed eaten than one that is increasing at 1lb. or less. The pig farmer ought to make more use of ashes. Pigs are often seen picking up all kinds of rubbish, and afterwards are found to be suffering from stomach trouble. This habit points to some deficiency in the food; the animals are looking for something to balance the ration. Those fed largely on maize will particularly develop a craving for rubbish. The remedy is a heap of ashes placed in a dry spot handy to the pigs. Pigs relish ashes, and the younger they get the habit of eating them the better. There will be no indigestion and no signs of constipation. There will be no pig eating if the sows have been brought up on ashes. It is a good thing to mix a little salt with the ash now and again." (Secretary, Mr. G. L. Tucker.)

**BUTE** (Average annual rainfall, 15.88in.).

August 21st.—Present: 10 members.

Mr. Trengove, in introducing for discussion the subject "Fodder Conservation," said, in good seasons, many farmers were apt to neglect this most important aspect of

## METTER'S "NUOIL" DOUBLE GEARED SELF-OILING WINDMILLS.

IN SIZES FROM 6ft. TO 14ft. WHEEL.

The strongest, best lubricated, best designed, and best governed.

Pump more water on a lighter breeze.

No spring on automatic oiling system to break, and no sheet-metal oil conveyors to wear out.

Gained First Prize and Silver Medal Adelaide Show, 1922, 1923, 1924, 1925, 1926, and 1930 (no entry 1928-29).

Also Gold Medal at the All-Australian Exhibition, 1930.

A reliable and useful investment, and the popular choice of experienced pastoralists, farmers, and others.

### METTER'S 5ft. "MINOR" WINDMILLS.

Most efficient for pumping water from shallow depths.

MILL ONLY, £9 15/0; on 15ft. G.I. TOWER, £15 15/0; on 20ft. TOWER, £17 17/6.

### METTER'S FUEL STOVES AND WASHING COPPERS.

Use less fuel and retain heat longer.

WHOLLY MANUFACTURED IN SOUTH  
AUSTRALIA BY

## METTERS LIMITED,

98, 99, 100, North Terrace,

ADELAIDE.

"NO FEAR OF A DROUGHT WITH A  
METTERS ABOUT."

farm management. It was always advisable to stack in heaps, well protected from the weather, as much cocky chaff as possible. During winter, cattle and young horses did very well on it. A stack of either barley or oats hay would also prove a valuable standby. A good discussion followed. (Secretary, Mr. L. Simon.)

#### KILKERRAN.

Thirteen members attended the meeting held on August 12th. Mr. A. Sawade read papers entitled "The Economic Position of the Farmer" and "Tractor v. Horses" from the *Journal of Agriculture*. A good discussion followed. (Secretary, Mr. A. S. Dutschke, Maitland.)

#### PASKEVILLE (Average annual rainfall, 15.67in.).

August 5th.—Present: 18 members.

**DRILLS AND THE COMBINE.**—Mr. W. Cox, in reading a paper on this subject, said the combine had proved of very considerable benefit to the settler on new lands, because of the fact that he could do two operations in one, save the expense of an extra machine and extra labor, and work over comparatively rough land. He gave preference to the spring tooth combine, because it made an ideal seed bed, and it was able to cope with rubbish, such as straw and bushes, much better than any drill. Again, with the combine, one was always up with the work; in wet weather, if using the cultivator and drill and a heavy rain fell, it would perhaps be some time before one could get on the land, and the fallow that had only been cultivated would in all probability have to be worked again. With the combine some farmers were inclined to expect too much from it, they asked it to do more than the machine was intended to do. They expected the combine to cut up a strong growth of weeds and still do justice to sowing the seed. If it could be avoided, the combine should not be used for working the fallow. The combine was a machine which was greatly abused. The tynes became strained when working hard ground, which resulted in the seed being buried unevenly and at too great a depth. The drill could be used to excellent advantage for sowing cereals for early feed on stubble land before rain. He inclined to the belief that crops sown with a drill gave better returns than those sown with a combine, but the advantage of the latter outweighed any increase in yield that might be obtained from the use of the former. (Secretary, Mr. J. Prouse.)

#### PETERSVILLE.

August 5th.—Present: Nine members.

Mr. R. Dutschke read a paper, "The Effect of Super on Crop Growth," which aroused an interesting discussion. Discussing the advisability of harrowing a growing crop during August, members were of the opinion that if the harrows were not too heavy and the ground not too dry, the harrowing would prove of benefit to the crop. (Secretary, Mr. A. Dutschke, Ardrossan.)

#### SOUTH KILKERRAN.

In the presence of a large attendance of members and visitors, an officer of the Royal Automobile Association delivered an address, illustrated with moving pictures. (Secretary, Mr. H. Schrapel.)

#### YORKETOWN (Average annual rainfall, 17.04in.).

August 12th.

The meeting took the form of a "Question Box." "Is it possible for pickled barley to come up without taking root?" *Answer:* "Yes, but it will not live." "When is it best to start shearing?" *Answer:* "The condition of the wool will help to determine that question. When the wool has a healthy appearance is the best time." "Does it pay to skirt fleeces?" *Answer:* "Yes, skirt lightly, and take out backs that are dirty." "Does it make any difference to the price of wool if bales are made to weight of 4cwts. or over?" *Answer:* "No." "What is a good remedy for a horse that is rubbing hair off itself?" *Answer:* "Get a stick of strong tobacco, put it in 1gall. of water, and bring this to the boil. Wash the horse with this solution, and it will effect a cure." "What is the correct amount of wheat to sow in this district?" *Answer:* "The season is the leading factor. If it is a dry season and late, 80lbs. to 90lbs. of the late varieties, 90lbs. of early varieties. If the season is favorable, 60lbs. of stooling varieties and 90lbs. of those that do not stook greatly was advised. The same remarks apply to barley. The character of the seed has a marked effect on results, especially under favorable conditions." "Does it pay to prune tomato plants?" *Answer:* "Yes. The Early Dwarf is one of the best varieties for this district." "Is horse manure best for cucumbers?" *Answer:* "No. Pig manure is better, because it is not so heating. Sow tomatoes on a patch that has had cabbages on it as previous crop." Mr. A. Heitmann explained the use of "hot-kaps" and their advantage. (Secretary, Mr. C. Stead.)

**WEAVERS (Average annual rainfall, 17.03in.).**

Meeting held July 14th at Mr. F. Anderson's homestead. The following papers were read:—"The Open Market for the Disposal of Farm Produce," Mr. L. Slade, and "Pooling Farm Produce," by Mr. F. Anderson. A keen discussion followed. Twenty-two members and four visitors attended. (Secretary, Mr. H. Cornish, Stansbury.)

**WEAVERS (Average annual rainfall, 17.03in.).**

Mr. C. F. Anderson (Acting Poultry Expert) delivered an address, "Eggs and Poultry," at the meeting held on August 11th, which was attended by 17 members and four visitors. (Secretary, Mr. H. Cornish, Stansbury.)

**WESTERN DISTRICT.****GOODE.**

**INSURANCE AGAINST DROUGHT.**—The following paper was read by Mr. A. Brown:—"Farmers of Australia as a whole have had very lucrative seasons. But it cannot be denied that lean seasons or absolute failures have also been the lot of the Australian farmers. Having these two extremes in mind, it is a matter of wonder to me that among all the farmers who have suffered these periodical losses someone has not thought of a way to provide during their bounteous seasons for the lean years which are sure to follow. We have very good examples in the friendly societies where the members, though not sick or ailing in any way, put their equal share into a fund to enable them when sickness comes to pay for their doctors and medicines, and also draw sufficient out per week to keep the house going during their illness. Had the farmer started on the same lines, say, 20 years ago, a huge sum of money would now be available. Anyone who has gone through the last four years and suffered the hardships which this prolonged drought has entailed, will agree that although the State Bank and the Government have done their very best for the drought-stricken farmer, an insurance fund of their own, where they were fully entitled to draw a certain sum per acre sown, would be very much preferable to asking the State Bank for advances or the Government to assist. By the latest reports it seems that it is not only droughts that we have to provide against, but prices of wheat, which stand to-day 50 per cent. under production cost. The remedy lies, in my opinion, in insuring against loss by drought, or loss by prices being below production costs. I will, therefore, commence by using as an illustration a 48,000,000bush. harvest in South Australia; I would then, by Act of Parliament, compel all farmers to leave with the pool or the merchants 1d. per bushel, that would amount to £100,000. The Government would be asked to subsidise this amount by 10s. in the pound. This amount would be loaned to the Government for three years, adding the same amount to it each year plus interest. At the end of the three years we would have just on half a million pounds. With that capital we could commence to operate, as cost per acre also returns per acre varies in different localities, so, of course, would returns per acre from the insurance fund also vary. In localities around here I consider 500 acres as much as a man can handle at seeding time on his own. Properly put in that man should receive 10s. per acre (£250), or equal to £5 per week, if a total failure is recorded. In other localities, where the cost of working the ground and extra seed and super is required, the returns should be up to £1 per acre per year. It must be here understood that any sum drawn for sale of wheat would be deducted from this amount. Should any farmer be in the happy position of not having to draw at all, a bonus at the end of each five years would be paid to him. Extra allowance would be made for farmers with help for extra acreage, approximately 5s. per acre between the 500 acre and 1,000 acre mark. The present agricultural instructors would be the judges in their respective districts to see that proper attention would be given to the preparation of the land and the seeding thereof."

**GREEN PATCH (Average annual rainfall, 26.56in.).**

August 7th.—Present: 10 members.

Replying to a question as to whether top-dressing had any effect on increasing the size of sheep, most members were of the opinion that since applying artificial manure to pasture lands in the Green Patch district the size of the sheep had considerably increased. Mr. P. Sinclair said it was difficult to increase the quantity of the wool and quality of the fleece without decreasing the size of the carcass. *Codlin Moth*.—This subject was also introduced for discussion. It was reported that although in some instances stronger solutions of arsenate of lead had been sprayed on the trees, codlin infested fruit was still in evidence. As a further precaution it was suggested that cases which had contained fruit should be dipped in a solution of salt and water. (Secretary, Mr. C. Whillas, Port Lincoln.)

**KYANCUTTA.**

The inaugural meeting of the above Branch was held on August 12th. Twenty-four names were enrolled as foundation members, and six new members were added to the list at this meeting. Mr. F. Daniels was elected Chairman and Mr. D. Fitzgerald Secretary. It was decided to hold meetings on the first Tuesday in each month, and that for the months of December and January the Branch would go into recess.

**MALTEE.**

At the Annual Meeting of the Branch, which was held on August 7th, the report of the past year's work was presented by the Secretary, and officers elected for the ensuing term of office. (Secretary, Mr. E. Schwarz.)

**MILTALIE** (Average annual rainfall, 13.89in.).

The annual meeting of the Branch was held at the residence of Mr. D. Ramsey. The President (Mr. P. Story) presided over an attendance of 17 members and 15 visitors. The Secretary (Mr. G. Smith, of Cowell) presented the annual report, which showed a gratifying increase in the attendance at meetings from eight to 14.

**MOUNT HOPE.**

August 5th.—Present: Nine members.

**ADVICE TO SHEEP OWNERS.**—In a paper on this subject, Mr. D. Speed said much publicity had been given to the necessity for advancing the wool industry, and the public were quite familiar with the slogans "Wear more wool" and "Use more wool." The speaker thought that some attention should be given to the need for developing a higher-priced wool. The fine-woolled sheep produced a heavy fleece. A point that growers would do well to bear in mind was the importance of marketing wool of a uniform quality. Wool of the latter type was certain to realise the best price. Their district was ideal for the production of a fine medium type of wool, and farmers should mate their flocks with that object in view. The Secretary, Mr. J. Vigar, presented the annual report, and officers were elected.

**PYGERY.**

August 5th.—Present: 19 members.

An instructive paper setting out the good points of the various makes of combines and drills was presented by Mr. G. Duggin.

On July 16th a large number of members and visitors attended a wool-classing demonstration given by Mr. C. A. Goddard, of the School of Mines, at the homestead of Mr. E. Edmonds. In the evening Mr. Goddard spoke on "Classing the Farmers' 'Clip.'" (Secretary, Mr. A. Day.)

**RUDALL** (Average annual rainfall, 12.14in.).

August 5th.—Present: 12 members.

**FALLOWING.**—In a short paper on this subject, Mr. H. Henderson said fallowing should commence as early as possible after seeding. The first working should be done with a medium weight plough, turning the soil to a depth of 2½ in. to 3 in. After all stumps, stones, &c., had been picked, the fallow should be worked with a spring-tooth cultivator, working across the ploughing. Following every rain, the cultivator should be used to assist in the conservation of moisture. Each working should be slightly shallower than that of the previous cultivation. If it was not possible to get on to the fallow after rain, sheep could be used to keep weeds in check. The meeting was held at the residence of Mr. B. Crabb. (Secretary, Mr. J. McKinnon.)

**TABAGOBO.**

The annual meeting was held on August 7th, there being present 18 members. Following the report of the Secretary and the election of officers a discussion took place on shearing and wool classing. (Secretary, Mr. T. W. Winters, Cleve.)

**WARRAMBOO.**

August 5th.—Present: 21 members.

**FENCING.**—Reading a paper on this subject, Mr. D. McKenzie said some landholders inclined to the opinion that fencing was a job to be done only when there was no other work to do on the farm. Good fences were an essential factor in the management of a well-equipped farm. Anyone who had had experience with straying stock would know the annoyance caused by fences in bad repair. The choice of material played a very important part in the construction of a fence. All posts should be of the same height, set in as straight a line as possible and at equal distances apart.

That could be done without any trouble if a chain was used. A fence 3ft. 6in. high was usually sufficient to keep most livestock within bounds, but an extra 2in. was advisable for the boundary fence. The wires in a fence 3ft. 6in. high should be spaced as follows:—Ten inches between the barb and top plain wire, then 8in., 7in., 6in., and 5in. between each succeeding wire, with the bottom wire 6in. from the ground. For a permanent fence, he recommended 12½ gauge high-tension wire, provided the strains were not made too tight. Struts were essential, and they should not be too short, otherwise they were inclined to lift the posts when the wires were strained. A good plan was to put in a post about 10ft. from the strainer, and place the strut against the bottom of it and between the two top wires of the strainer, when it would be impossible to pull over the strainer post when straining the wires. A forked stick with a hole bored in the end made an efficient straining tool. When boring, the holes should be bored in the direction in which the fence was running, otherwise it would be difficult to pull the wires through the posts. In stony country, iron droppers could be used to advantage. A strong fence under such conditions could be erected by placing four iron droppers between wooden posts placed 20ft. apart. In rebuilding an old fence, old wire should be carefully examined for rusted places. All spare pieces of wire should be collected and taken out of the paddocks. Gates in the fences should be wide enough to allow a team to pass through, and gates in regular use should be so constructed that they could be opened and shut with ease. Fences should be attended to regularly, broken wires repaired, and posts replaced where necessary. Shoots and other rubbish should be cleared away from fences to prevent the collection of drift.

FENCING.—The following paper was read by Mr. P. Palmer:—"The erection of permanent fences will eventually save the farmer time and money. If the holding is pestered with rabbits netting is, of course, the best material to use for the fence. With a plain wire along the top of the netting and another 12in. from the ground, the netting will not be dragged up should sheep run over it. If there were no rabbits to contend with, then cyclone fencing is recommended. This type of fence will not be covered with drift, and it can be erected in less time. Five plain wires with a barb on top also makes a very satisfactory fence. As to the height, I consider 3ft. 6in. the ideal. Good posts not less than 5in. in diameter at the top and placed every chain or 25yds. with five heavy flat-iron droppers between makes an excellent foundation for a fence. A good pair of pliers and a strong straining jack that can be used between strains for effecting repairs are necessary tools for the fencing equipment." Discussing the papers, Mr. P. Daniels said in strutting the strainers it was better to place the strut low down on the post. If that was done it did not interfere to the same extent with the boring of the post and pulling in the wires. Mr. A. Turner supported the argument of the writer of the paper that the higher the strut was placed on the strainer the better. Mr. O. Murphy said the strut should be placed at an angle of 45°, and it would not allow the strainer to lift. He considered that a six-wire fence could be erected more cheaply than a cyclone fence. Discussion took place on the use of concrete posts, the general opinion being that to manufacture them would prove too expensive. Mr. F. Chilman referred to netting fences and admitted that if rabbits were bad they were almost a necessity, but their great disadvantage was that buck bush collected against them, and if drift was bad the fences soon became ineffective. Mr. J. Sampson emphasised the importance of placing the bottom wire of the fence sufficiently low to keep sheep from crawling underneath it. (Secretary, Mr. E. Adams.)

#### WUDINNA (Average annual rainfall, 13.68in.).

Eleven members and three visitors attended the meeting held at Mr. Johnson's residence on August 4th. The Hon. Secretary (Mr. C. Newbon) read a report of the work performed by the Branch during the past year, and officers were elected.

### EASTERN DISTRICT.

#### (EAST OF MOUNT LOFTY RANGES.)

##### BLOCK E.

August 12th.—Present: 14 members.

Mr. L. White gave an interesting talk on "How to fill in income tax papers." Mr. C. P. Smith, who with Mr. P. John has always judged this Branch's Pruning Competitions, presented the pruning cups and trophies to this year's winners: Mr. A. Pietsch first in vines and Mr. M. Pethick second; Trees: Mr. M. Pethick first and Mr. A. Nenke second. Mr. C. P. Smith offered to donate a prize next year to the best competitor in the pruning competitions who has not previously won a prize, to try and encourage more competitors. He also offered to give pruning demonstrations. As an

appreciation of past services to the Branch Mr. W. Edmonds, on behalf of the Branch, made a small presentation to Messrs. Smith and John. Mr. M. Pethick donated a cup for the best green manure crop. (Secretary, Mr. H. Davies, Renmark.)

#### BOOLGUN.

August 7th.—Present: 16 members.

**FENCING AND SUBDIVIDING THE FARM.**—In a paper on this subject Mr. T. Spencer, for the boundary, recommended a fence consisting of posts 5yds. apart with 20 posts to each strain, five plain and one barb wire. Strainer posts should be 9in. to 12in. in diameter, placed at least 3ft. in the ground and supported by strong struts. The height of the fence should be 3ft. 6in., and the wires spaced as follows from the ground level:—The first four wires each 6in. apart, the fifth 8in., and the barb placed on top of the post, 10in. above the last plain wire. If posts were difficult to obtain, they could be placed half a chain apart, and two or three wooden droppers used between each post. The subdivision of the farm should be so planned as to permit of easy stock watering facilities. He preferred paddocks of about 100 to 150 acres in area, with two or three paddocks containing not more than 40 or 50 acres. Plenty of gates should be provided, and these should be wide enough to permit the passing through of the largest implements on the farm without having to unyoke the team. He advised six wires for the gates, making them 6in. above the fence. If at all possible, one should avoid running the division fences over sandhills. These latter fences should be 3ft. 3in. high, with four wires and one barb, spaced as follows:—7in., 7in., 7in., 8in., and 10in. If plenty of posts were available, place them 5yds. apart. Barb wire should be tied to the posts. Last, but not least, "do not forget to leave shelter belts or clumps of trees for shelter for the stock." Mr. Spencer advised cutting timber for posts during June and July. (Secretary, Mr. J. Palm.)

#### BRINKLEY.

Eighteen members attended the meeting held on August 6th. Mr. L. Rust read a paper, "Experimental Farms and Their Value." A good discussion followed. (Secretary, Mr. C. Pearson.)

#### BUGLE.

General business was transacted at the meeting of the Branch held on August 26th, which was attended by Mr. J. S. Todd (Chair), 12 members, and two visitors. (Secretary, Mr. B. Auricht, Taldra.)

#### CALIPH.

Meeting held August 5th. Present: 10 members. Mr. J. Burnett read a paper, "The Most Profitable Utilization of Sheep on the Farm," which aroused a keen and instructive discussion. (Secretary, Mr. W. Todd.)

#### CLANFIELD (Average annual rainfall, 16in. to 17in.).

Meeting held August 13th. Present: Eight members and a large number of visitors. The Deputy Director of Agriculture, Mr. W. J. Spafford, addressed the meeting. (Secretary, Mr. W. Pearce.)

#### COPEVILLE (Average annual rainfall, 11.58in.).

Meeting held August 13th. Present: Mr. J. Collins (Chair), eight members, and a large number of visitors. Mr. C. Goddard, of the School of Mines, gave a demonstration and lecture on wool classing. (Secretary, Mr. G. Sutherland.)

#### KANNI, August 9th.

There was a good attendance of members and visitors at the August meeting. Discussing the question of sidelines on the farm, sheep, cows, and pigs, were considered to be the most profitable. The Merino sheep was favored, and cows would prove a valuable asset providing the attention which they demanded did not make too great a call on the time of the man who had to look after the teams. A member spoke on the advisability of conserving fodder in the form of ensilage. (Secretary, Mr. F. Woodland, Waikerie.)

#### KULKAWIRRA.

The meeting held on August 11th was attended by 19 members and nine visitors, when addresses were delivered by Messrs. W. J. Spafford and R. L. Griffiths, of the Department of Agriculture. (Secretary, Mr. H. Elliot, Karoonda.)

# THE IMPLEMENT CO.

Offer a Complete Line of

## Harvesting Machinery

Don't risk a whole year's work when you can ensure against loss by getting light running, easily handled harvesting machinery on which you can always depend to harvest and market your crop. You will find in the Implement Co. line the finest materials and workmanship—and, what's best of all, years of satisfactory service.

**HORWOOD-BAGSHAW  
"GASTON" HEADER.**

The simplest, easiest running, and most effective Reaper Thresher in Australia. Sizes, 8ft. and 10ft. cut. This machine has fully earned its name—"The Better Built Header."

**HORWOOD-BAGSHAW  
"ILLMAN" STRIPPER.**

The Horwood-Bagshaw "Illman" Stripper is the result of many years close attention to the requirements of Mallee Farmers, and we are confident in offering this machine to fill the demands of the most exacting user. Made in 8-ft., 9-ft., and 10-ft. sizes.

~~~~~  
Write for catalogs and prices of the above, also "Horwood-Bagshaw" Winnowers, "Austral" Binders, "Horwood-Bagshaw" Wheat Elevators, "Frost & Wood" Hay Rakes and Hay Balers.
~~~~~

# THE IMPLEMENT COMPANY

**BANK AND BLYTH STREETS, ADELAIDE.**

**LONE GUM AND MONASH.**

Mr. J. Brown presided over an attendance of 19 members at the meeting held on August 4th. A report of the past year's work was presented, and officers elected for the forthcoming year. (Secretary, Mr. R. Nancarrow, Lone Gum.)

**LOWBANK.**

Twelve members attended the Annual Meeting, which was held on August 4th. Following the presentation of the Secretary's annual report, officers were elected and a programme of meetings arranged. (Secretary, Mr. L. Geyer, Waikerie.)

**MARAMA.**

Fourteen members and two visitors attended the meeting held on August 5th, when Mr. R. L. Griffiths (District Agricultural Instructor) delivered an address, "Wheat Varieties." (Secretary, Mr. T. Hinkey.)

**MERIBAH (Average annual rainfall, 11.70in.).**

August 11th.—Present: 17 members.

**SAND IN HORSES.**—Discussing this subject, Mr. W. Mason recommended the use of sand powders. Mr. W. Young had had good results with coffee. Messrs. L. Galley and C. Wishart pinned their faith to carbonate of soda and ginger. Other matters of local interest were discussed. (Secretary, Mr. E. Carr.)

**MILLENDILLA (Average annual rainfall, 13in.).**

August 4th.—Present: Seven members.

**CONSERVATION OF FODDER.**—A paper on this subject was read by the Secretary, Mr. V. Wegener. In the discussion that followed it was stated that the main fodder for conservation in this district was wheaten hay, well stacked and covered, and if it was to be kept for a period of years it was advisable to put a galvanized-iron fence around the stack. This should be let well into the ground, several feet out from the stack; if, when placed against the stack, straw or hay falling down fell against the outside of the fence and provided a means for the mice getting back into the stack. It was thought that straw would keep better than cocky chaff if the latter was kept longer than two years. With age straw became softer and was relished better by stock. Cocky chaff was of very little value for feed after the second year. Several members said that putting salt between each layer of hay or straw as it was put down also kept out mice, besides greatly increasing the feeding value. The Secretary said that every farmer should erect a stack of straw in the paddock which, during rough weather, provided shelter, and even in a good season some was eaten by the stock. He had noticed that his sheep were eating the straw he had conserved from the last harvest, especially during wet weather. The trouble with most farmers was that after a drought they made a good start by conserving fodders, but after a few years forgot all about droughts. There were also some farmers who, owing to financial difficulties, were unable to cut much hay, because they had to gather every bushel of wheat possible to meet their creditors. Such a thing should be avoided if at all possible, as it did not pay. **QUESTION BOX.**—"Is it likely that a paddock containing mustard would flavor the meat of sheep if grazed off by them?" If the sheep to be killed were taken off the mustard several days before killing, then the meat would be free from the flavor of the weed. "Why do weeds germinate better on land that is ploughed, drilled, and harrowed than if only ploughed and left as fallow?" The extra working encouraged germination. Some farmers were using the cultivator, scarifier, or combine for fallowing this year, which seemed to give a quicker and better germination of weeds, besides reducing production costs and minimising drift. Fallowing was done earlier and quicker, which was an advantage in a late season. This practice will be watched with interest, as it is still in the experimental stage with some farmers in this district.

**MOORLANDS (Average annual rainfall, 14.76in.).**

Nine members and three visitors attended the meeting held on August 19th, when the District Agricultural Instructor (Mr. R. L. Griffiths) delivered an address, "Cultivation and Rotation of Crops." (Secretary, Mr. L. Ortloff.)

**MYPOLONGA.**

June 23rd.—Present: 11 members.

The Secretary presented the annual report, and officers were elected for the ensuing 12 months. The Annual Pruning Competitions were held on July 3rd in Messrs. Victory's and Foster's orchards. Mr. E. Leishaman (District Instructor) acted as judge, and

Messrs. K. Dowding and B. Pickering assisted as consultative judges. Mr. A. Wedd secured the highest aggregate in trees and vines, Mr. A. Burrett second, Mr. A. Milde third, and Mr. N. Angrave fourth.

A further meeting was held on July 30th. The meeting took the form of a debate on the subject, "Orchard Work v. Dairying," and papers in support of the orchard were read by Messrs. Pickering and Edson; the value of cows on the orchard was supported by Messrs. Noles, Hill, Prosser, and Collins. (Secretary, Mr. L. Haynes.)

#### NETHERTON.

Meeting held August 6th. Present: 14 members. Mr. R. L. Griffiths (District Agricultural Instructor) delivered an address, "Wheat Varieties for the Mallee." (Secretary, Mr. C. Wilkin, Yumali.)

#### NUNKERI.

Meeting held August 6th. Present: 15 members. Mr. H. Sanders read an instructive paper, "The Farm Water Supply." A good discussion followed. (Secretary, Mr. F. Ling.)

#### KYBYBOLITE EXPERIMENTAL FARM.

Farmers' Day, November 13th, 1930. Visitors inspecting Pasture Plots.

#### OVERLAND CORNER (Average annual rainfall, 10.58in.).

Mr. J. Atkinson presided over an attendance of 15 members and four visitors at the meeting on August 5th, which was held at the residence of Mr. J. Loffler. An address, "Hints on the Management of Sheep," was delivered by Mr. Raggatt, of Morgan. (Secretary, Mr. H. Loffler.)

#### PARUNA.

The meeting of August 1st was attended by the Chairman (Mr. A. Webb) and 20 members. After the annual report had been presented by the Hon. Secretary (Mr. F. Sumner) and the election of officers had taken place, a paper, "Tractive Power and Farm Machinery," was read by Mr. A. Patterson.

#### PINNAROO.

The meeting of August 13th took the form of a social evening. Addresses were delivered by Messrs. F. Coleman and P. H. Jones, of the Advisory Board of Agriculture, and Mr. H. C. Pritchard, General Secretary of the Agricultural Bureau. Musical items were contributed, and supper was provided by the members of the Pinnaroo Women's Branch. (Secretary, Mr. H. Badman.)

#### PINNAROO WOMEN'S.

The Annual Meeting of the Branch was held on August 1st, and was attended by the President (Mrs. Dowd) and 13 members. The annual report was read and the election of officers followed. (Secretary, Mrs. F. Atze.)

**RENMARK (Average annual rainfall, 10.60in.).**

Members and visitors to the number of 48 attended the meeting held on August 11th, when addresses were delivered by Messrs. H. B. Barlow and P. H. Suter, of the Dairy Branch of the Department of Agriculture. Mr. A. Hilton, of the Murray Bridge Agricultural School, also addressed the meeting. (Secretary, Mr. W. Meier.)

**WAIKERIE (Average annual rainfall, 9.71in.).**

Fourteen members and eight visitors attended the meeting on August 15th. Addresses on the subject of keeping a few cows in conjunction with fruit growing were delivered by Messrs. H. B. Barlow and P. H. Suter, of the Department of Agriculture. (Secretary, Mr. E. Rowe.)

**WILKAWATT WOMEN'S (Average annual rainfall, 16in. to 17in.).**

Twelve members and 14 visitors attended the meeting held on August 8th, when Miss E. Campbell, Dip. Dom. Econ., of the Education Department, delivered an address, "Home Dressmaking and Fancy Stitchery." (Secretary, Mrs. A. Oram.)

August 19th.—Present: 12 members and eight visitors.

**THE HOME ATMOSPHERE.**—Mrs. H. Billing read the following paper:—"A good housewife will not rest content with the fact that her meals are well cooked. She will also see that they are well served, knowing that dainty table equipment and skilful service do much to enhance the enjoyment of the fare provided. No matter how simple a meal may be, it should be placed neatly upon the table and made attractive to the eye. The decoration of the meal table should be confined to such decorative needle work as will launder, together with the glint of the silver and glass ware (both as good of its kind as can be afforded), the prettiness of the china, and flowers, and foliage which are always in good taste. If amongst these are placed temptingly arranged dishes, the table will look not only attractive, but also hospitable. Remember the motto, 'A housewife's art is displayed in a table well laid.' The clean cloth, the bright silver and glass, the tidy and pleasant room—well ventilated—with tasteful floral decorations, will add to the enjoyment of the meal. The table is the special centre of most homes. Certain table refinements are amongst the ameliorating influences which help to cultivate the mind and improve manners." (Secretary, Mrs. A. Oram.)

**YURGO.**

August 4th.—Present: Eight members and six visitors.

**FALLOWING.**—The following paper was read by Mr. J. Bullen:—"Fallowing is a system of cultivation which assists the soil to store moisture and make food available to plants. It also helps to control plant diseases and prepare a seed bed for the coming season's crop. Before ploughing, see that the land to be fallowed is free from rubbish. Sheep will assist in this direction and increase the fertility of the soil by converting weeds into manure. The droppings enrich poor soils, and the beneficial effects of sheep on sandy soil cannot be over estimated. For fallowing I favor the mouldboard plough. It buries all weeds and makes a level seed bed. Depth of ploughing will be governed by the nature and condition of the soil, and also the time of fallowing; usually sandy soils can be ploughed at a depth of 2in. to 3in., and clay loamy soil 3in. to 4in., the depths to be reduced if for a short period fallow. If a loamy soil crumbles readily in the hand it is generally in good condition for ploughing, but sandy land can be ploughed wet. Work up the clay and loamy soils first, they are capable of holding more moisture and are richer in plant foods. Clay or loamy soils should not be ploughed when too dry, because it requires more power, turns up large clods of earth, and does not invert the furrow into a mellow, crumbly condition. The next operation is harrowing crossways to the plough, to break down all clods, fill in air pockets, and level the surface. Fallow should be worked after every rain. I favor at least one working with the cultivator and two workings with the harrows, but this must be done after a rain. For a working with the cultivator, not less than  $\frac{1}{2}$  in. of rain must have fallen. Cultivating destroys weeds and prepares a firm seed bed. When cultivating do not go deeper than 1 $\frac{1}{2}$  in. to 2in. Any type of cultivator will do to work the fallow, so long as it is in good order. Avoid using a disc implement, because the depth of working cannot be regulated. If the land is inclined to drift, do not use the harrows after the first working, and work crossways with the cultivator to the direction of the prevailing winds. Do not put sheep on fallow that have been grazing on stubble of a diseased crop. Well worked fallow should not require grazing with sheep." (Secretary, Mr. M. Walker.)

**SOUTH AND HILLS DISTRICT.****BLACKHEATH.**

At the meeting of the Branch, held on August 14th, there were present Mr. H. Paech and 11 members. The annual report and balance-sheet were presented and officers elected for the ensuing term of office. Mr. Law read portion of the Departmental Bulletin, "Pig Raising." (Secretary, Mr. E. Paech, Rockleigh.)

**CHERRY GARDENS (Average annual rainfall, 35.03in.).**

The meeting of August 2nd was held at the residence of Messrs. H. and K. Jacobs, there being present 12 members. Members inspected the apiary, vegetable and fruit garden. A pruning demonstration was given by Messrs. I. and A. Stone and K. Jacobs. A flock of ewes with lambs at foot was favorably commented upon. Afternoon tea was provided by the ladies. (Secretary, Mr. A. Stone.)

**GUMERACHA (Average annual rainfall, 33.54in.).**

Meeting held August 4th. Present: 12 members and two visitors. Mr. S. Cornish read a paper, "Farm Buildings," and a good discussion followed. (Secretary, Mr. L. Wise.)

**KANGARILLA WOMEN'S.**

The subject for the meeting held on August 14th was "Household Hints." Seven members attended, each of whom brought forward a useful hint in connection with women's work on the farm. (Secretary, Mrs. M. Steer.)

**MOUNT BARKER AGRICULTURAL BUREAU.**

Field Day, October 22nd, 1930. The Chief Dairy Instructor (Mr. H. B. Barlow) explains the good points of a Dairy Cow.

**LANGHORNE'S CREEK (Average annual rainfall, 14.84in.).**

August 6th.—Present: 14 members and three visitors.

Mr. C. A. Whittlesea provided an interesting paper, "Fallowing," which promoted good discussion. Mr. Dodd asked why deeper ploughing for sand was advocated? In reply Mr. Whittlesea stated that heavy land was too sour, whilst in many sands deeper ploughing brought up heavier land. Mr. Natt inquired whether reploughing was advisable? The writer said that unless weeds had so much hold that ploughing was the only effective method, reploughing was not advisable. (Secretary, Mr. H. Pollett.)

**LENSWOOD AND FOREST RANGE (Average annual rainfall 35in. to 36in.).**

August 25th.—Present: 10 members.

**PACKING AND EXPORT OF APPLES.**—Mr. G. Schultz read the following paper:—"Many people overlook the importance of packing if the best returns are desired. As an example, take two cases of apples; one with the top uneven, an apple here and there showing bare, and plenty of ends of paper sticking up; the other with the top level, every apple well wrapped up, and the loose ends hidden. Will not the case that is

well packed bring more than the other in the open market? The price of packing is 5d. per case. Let us assume that a man is packing 60 cases a day. One grower will say to the packer, "You are making too much money, you will have to pack for 4d." The packer rushes the work and packs 75 cases to make the same money; needless to say, he does the sort of job we had in mind first. Another man will say, "Make a good job and I will pay accordingly." The packer does 50 cases and gets 6d. per case. Which grower is going to make the most profit? Further, it is easier to pack 50 cases really well than 60 cases fairly well or 75 cases in a slipshod manner, and so the job becomes more attractive to the packer and he will be looking for a job next year. It is not suggested that the grower will automatically receive 2s. per case extra if he pays 1d. per case more for packing, but if good packing is done generally, packers would soon become more plentiful and growers would be in a position to demand better packing. It would not cost much per case to make the work so attractive that packers would pack just as one wanted them to, rather than lose the job. One side of the question must not be forgotten; it is a job that only lasts a few weeks and, in South Australia at any rate, only every other year. Most men leave regular work to take it on, so the job must be made attractive if we are to get good packers. Having good packers, it is necessary to bring them good fruit, well graded to pack. The best packer cannot put fruit in the cases in good condition if it is brought to him bruised in the picking or grading. There is more harm done to apples before they reach the packer than after. This is where we have lost our profit in export apples. I have packed Jonathans, good color, well matured, and quite clean, as good apples as could be desired, and they were sent away on the same consignment, under the same brand, with nothing to distinguish them from apples that were almost green with plenty of scab. I have seen apples badly withered sent with apples in first-class condition. This leads to the probability of opening one case of apples and finding it good, buying a parcel on that sample, and finding the rest green and scabby or withered. There is no need to say what happens. The costs on apples overseas are about 7s. 6d. per case, so that the grower must realise about 11s. per case before he starts to reckon his profit, and he has no right to expect anyone to pay that for them unless the fruit is put up in first-class condition. Under present conditions there is a wide range of apples that can be placed under standard grade. Before we can expect anything like top price for our apples, we will have to put them up in more grades, so that a buyer when he opens a case or two will know what to expect from the whole consignment. Again, we brand our cases with the size of the apples, while the buyers are asking for the count. This means better sizing. Grading to 1/4's is reliable enough for counts; they would have to be graded to 1/8ths. I have heard growers say this year "South Australian apples are bringing nearly as much as those from New Zealand." Is there anything to be proud of in the fact that New Zealand, a country that started on this export trade 30 years after us, is beating us at it? Is there any reason why New Zealand growers should get a better price for their apples than we get for ours? I am not prepared to admit that they grow better apples. Then they must put them on the market in a more attractive way. If they can do it, so can we. We hear on all sides of the improvement in this year's apple pack. It will be agreed that it was not in the apples themselves. Then where was the difference? A little in the style of packing and the rest in a better case. When one hears growers refer to making 2s. per case on these two items, it makes one wonder what growers would get if the apples were picked carefully and graded well. It seems we have gained a little on New Zealand and Western Australia this year, but there should be no excuse for being behind them at all." (Secretary, Mr. B. Laurence.)

---

MACGILLIVRAY (Average annual rainfall, 19in. to 20in.).

Meeting held August 12th at the residence of Mr. H. Seager. Present: Five members and visitors. Matters of a formal nature were brought forward for consideration. (Secretary, Mr. J. Wood.)

---

MONARTO SOUTH (Average annual rainfall, 14in. to 15in.).

August 16th.—Present: 34 members.

CARE OF THE BREEDING EWE.—Mr. R. Frahn read the following paper:—"In this district, ewes should be mated about the end of November or the beginning of December; about 70 to 80 ewes per ram if the rams are healthy and in good condition. Ewes should not be too fat when mated. After mating, they should have plenty of exercise and not too much feed. Grazing on hilly country is preferred; this will keep them strong and healthy. Crutching should be done about four weeks before lambing and

the wool removed from the udder, especially around the teats, to give the lamb every chance of sucking immediately it attempts to do so. Always have a good paddock in reserve with plenty of feed, and when the ewes start lambing turn them into it. Through the summer good, clean, stock water is essential. A mill tank and troughs are best; the troughs should be cleaned out whenever they become dirty. Troughs near roads are of little use; they are often used as bathing pools by dogs and the sheep will be disturbed. Farmers often make the mistake of having the breeding ewes in a weak state, and when they lamb foxes begin to trouble them. Often the fox is not to blame for dead lambs lying about the paddock. With poor, weak ewes, there are always a few lambs that die after birth, and that is when foxes become troublesome. If ewes are healthy and strong, they will be able to rear good, healthy lambs and will, to some extent, be able to protect them from danger. Every care should be taken when crutching ewes in lamb." For the breeding of lambs for slaughter, Mr. A. Braendler favored the Dorset-Merino cross. The Suffolk-Merino cross also produced good lambs. All agreed that the Shropshire-Merino cross lamb was excellent, but trouble was experienced at lambing time, because that lamb had an exceptionally large head and many ewes had to be assisted. (Secretary, Mr. F. C. Altmann.)

#### KEITH AGRICULTURAL BUREAU.

Field Day, November 11th, 1930. Crop of Peas on the property of Mr. A. W. Shannon.

#### SCOTT'S BOTTOM.

The meeting of August 9th was held at the residence of Mr. J. Blakely, and was attended by 10 members. An instructive paper, "Grasses for the District," was contributed by Mr. Brenton. (Secretary, Mr. E. Atkinson, Cherry Gardens.)

#### SPRINGTON.

August 6th.—Present: Eight members.

CULTIVATION OF THE VINEYARD.—Mr. E. Brokate read a paper on this subject, and in the discussion that followed the general opinion of members was that the soil should be ploughed to a depth of 4in. or 5in. at the end of August or early in September, then harrowed and cultivated or scuffed four or five times. The harrows were considered to be the chief implement, and should be used freely. Hoeing would also assist in keeping weeds under control. (Secretary, Mr. E. Brokate.)

#### STRATHALBYN (Average annual rainfall, 18.22in.).

Meeting held August 5th. Present: the Chairman, Mr. C. Lund, and a good attendance of members and visitors. Mr. F. Coleman (Chairman of the Advisory Board of Agriculture) delivered an address, "Fallowing and Seeding." (Secretary, Mr. F. Allison.)

#### TWEEDVALE (Average annual rainfall, 36.08in.).

On the occasion of the annual meeting, which was held on August 14th and attended by 18 members and visitors, the Hon. Secretary, Mr. B. Schapel, presented the annual report, and officers were elected for the ensuing year.

# CROWN LANDS.

---

## LANDS OPEN TO APPLICATION.

Lands in the Hundreds, as shown below, are open to application until 3 p.m. on Tuesday, January 13th, 1931.

Lands in the Hundreds of BARNA, BICE, BLACKER, BOOTHBY, BUCKLEBOO, BURGOYNE, CALDWELL, CHILLUNDIE, COCATA, COHEN, COLTON, COOTRA, CUMMINS, GILES, GOODE, HAGUE, HASLAM, HORN, KIANA, KOONGAWA, MITCHELL, MOSELEY, NICHOLLS, NUNNYAH, PEACHNA, PEARCE, PINKAWILLINIE, PYGERY, RIPON, RUSSELL, SOLOMON, TOOLIGIE, WALLALA, WANNAMANA, WOOKATA, WUDINNA, YALANDA, YANINEE, and YARANYACKA.

Full particulars are published in the *Government Gazette* of November 20th, 1930, and plans and detail may be obtained on application to the Director of Lands, Box 293A, Adelaide.

---

## LIST OF LANDS OPEN.

The attention of intending applicants for land is directed to the Official List of Lands Open, which is published half-yearly (in January and July). The list shows the areas, localities, prices, short general descriptions, &c., of the sections available, and the conditions under which they may be applied for.

Copies of the list may be obtained on application to the Director of Lands, Box 293A, Adelaide.

---

## APPLICATIONS FOR LAND.

Intending applicants for any lands which are open for application are reminded that application may be made for the whole or any portion of a block. The Land Board has power to allot portions of a block if considered advisable, and to adjust the purchase-money or rent. If only portion of a block is applied for, deposit of a proportionate amount must be made, and the successful applicant would be required to pay cost of survey of the subdivision.

---

## ADVANCES TO SETTLERS.

The administration of the various Acts dealing with advances to settlers has been committed to the State Bank of South Australia by the State Bank Act, 1925. All applications should be made to the Chairman, Board of Management, State Bank, Pirie Street, Adelaide.

R. S. RICHARDS, Commissioner of Crown Lands.

## AGRICULTURAL VIEWS AND COMMENTS.

### Registration of Dairy Farms.

The Minister of Agriculture (Hon. S. R. Whitford, M.L.C.), recently stated that the Government had given serious consideration to the position brought about by the decision of the late Government not to insist on dairymen registering their premises under the Dairy Industry Act. The provisions of this Act practically removed dairymen, except in the metropolitan area, from supervision by local boards of health and substituted supervision by the Dairy Department. The result of the late Government's decision on the matter was that, except in the metropolitan area, there had been no supervision of dairy farms at all during the past year.

Those portions of the State included in the metropolitan area, the whole of the West Coast, the counties of Albert, Alfred, Buccleuch, Chandos, Cardwell, and Carnarvon, the municipalities of Port Augusta, Davenport, and Quorn, the district councils of Coglein, Orreroo, Port Germein, Woolundunga, Hammond, Carrieton, Kanyaka, Hawker, and Morgan, are exempted from the Act. In any other part of the State it was unlawful for any person to carry on dairying unless the farm was licensed as provided in the Act, and the Government had decided that these provisions of the Act must be complied with. Fees were payable before July 1st last, but in view of the fact that the Act was not put into operation last year dairymen were given up to January 1st to apply for licences for the half-year ending June 30th, 1931, and to pay the necessary fees. The fee for the half-year was 3d. per cow, with a minimum charge of 5s. Where less than six cows were kept no fees were payable, but the dairy must be licensed. Under the Act, dairy farm means any land or premises where cows are milked or kept for the purpose of producing milk for sale either as milk, cream, butter, or cheese. Forms of application for licences were obtainable from the police officers at all stations within the area to which the Act applies, and also from the District Dairy Instructors.

### Agricultural Statistics.

The International Institute of Agriculture at Rome has recently published the "International Year Book of Agricultural Statistics." The volume contains 800 pages dealing with the world situation from the geographical, political, and demographical points of view, the apportionment of cultivated areas between different crops, agricultural produce, different kinds of livestock, yields, &c. A portion is devoted to the weekly quotations of 25 agricultural products in the principal world markets for 1913 and 1926 to 1930, as well as freight charges, statistics of production with the uses of fertilizers and their prices. Special chapters deal with the importance and distribution of the agricultural population and the distribution of agricultural holdings according to their size and mode of tenure and forestry.

### Sweden as a Market for Australian Produce.

An article on this subject appears in the *Swedish-Australian Trade Journal* under the pen-name of "Observer," who quotes the following statistics to show how Australian direct trade with Sweden has increased during the last 25 years:—

#### *Australian Trade with Sweden, 1904-1928/29.*

| Year.             | Imports.<br>£ | Exports.<br>£ | Total.<br>£ |
|-------------------|---------------|---------------|-------------|
| 1904 . . . . .    | 78,274        | 966           | 79,240      |
| 1928-29 . . . . . | 1,480,808     | 413,938       | 1,894,746   |

In addition to direct exports to Sweden, there is probably a very considerable Australian export to Sweden through other countries, regarding which there are no statistics available. The possibility of an extension of exports is discussed from the figures showing exports from Australia for the fiscal year 1928-29 and the imports

By virtue of its low first cost, low depreciation and low cost of upkeep, the New Fordson Tractor shows big savings when compared with horse-team work or with heavier, costlier farm tractors. The Fordson definitely reduces crop production costs.

## The Fordson is British built

The Standard Fordson

**£220**

at nearest Ford works

*Price Subject to Sales Tax*

**T**HE Fordson Tractor factory at Cork, Ireland, employs over 4500 Britishers. It is the largest industrial plant in the Irish Free State and the largest tractor factory in the world.

From this British factory come the supplies of the New Fordson Tractor for the whole world . . . an output of 160 Fordsons per day having recently been reached.

Raw materials used in Fordson construction are largely British—the majority being supplied from England, some from British Dominions, and a small proportion from European countries. Thus the Fordson, produced by British workers in the heart of the British Empire, is as thoroughly British as it is possible for a farm tractor to be.

Your nearest Ford Dealer can supply full particulars of the New Fordson, backed by facts and figures as to Fordson costs on your own type of farming operations. Let him arrange a demonstration of the British Fordson on your own field work.

## Tractor

INC.  
AUSTRALIA PTY. LTD.

into Sweden for the calendar year 1929. In the case of *Wool*, the imports from Australia are less than one-fifth of the total imports, and a considerable expansion in this trade seems possible. Sweden imports about £3,000,000 value of *Wheat*, and of this only £148,000 value is imported direct from Australia. With good seasons in Australia, increased exports to Sweden should be established. Next to the United Kingdom and Germany, Sweden was the most important market for Australian *Apples* during 1928-29. Direct exportations to that country amounted to £27,000; but in addition large supplies of the total Australian export were probably transmitted to Sweden through Great Britain and Germany. The total imports of apples into Sweden were almost equivalent to the total export of apples from Australia. There appears to be a growing demand for apples in Sweden, and as Australian apples reach that market when supplies from other sources are more or less depleted, the market for our produce may still be considerably improved. There should also be a much larger direct export of Australian *Hides* to Sweden, which imports a value of £960,000, of which Australia supplies, direct, about £16,000. Australia, again, should also be able to extend her exports of *Tallow*, in which Sweden has a fairly large import trade. Markets are also available for *Fresh Fruits* (other than apples), and the Australian trade with Sweden is small. The bulk of imported *Preserved Fruits* comes from the United States, and out of a total importation in all of £84,000, only £1,300 is credited to Australia. As far as Sweden is concerned it would be worth investigating whether it would not be possible to find a good market here for this class of product. Australia is not mentioned in the Swedish statistics of imports of *Hair* for 1929, although a very small quantity was actually sent in 1928-29, when the total value of Australian exports to all countries was about £29,000, which is a little more than half the total imports into Sweden. There seems also to be a direct market for *Sausage Casings*. Most of our export trade in this line goes to United States and Germany, both countries sending large quantities to Sweden. Out of the large export of *Sheepskins* from Australia only a very small value (under £200) was sent to Sweden in 1929. The Australian direct exports of sheepskins to Sweden appear too small when one considers the good market in this country, which imports a value of about £100,000. There have been small exports of *Honey* to Sweden, and as the price of the honey imported into that country is about twice that of the honey exported from Australia, there seems no reason why Australian honey could not be exported to Sweden. Markets are waiting for other products, such as *Dried Fruits*, *Oats*, *Wines*, *Furred Skins*, *Tanning Bark*, *Casein*, and *Metals*, as well as other lines, which, however, do not seriously interest this State. The members of the Swedish Chamber of Commerce are desirous of assisting Australian producers and exporters to find larger markets in Sweden. The writer affirms that of all the countries in Europe, Sweden appears to have been the least affected by the world depression, and her markets, therefore, should be able to absorb and pay for many of the commodities that now are a glut on other markets.

### **AGRICULTURAL INQUIRIES.**

[Reply supplied by Prof. A. J. PERKINS, Director of Agriculture.]

#### **Analysis of Pollard.**

Two samples of pollard, one lighter in color than the other and costing 2d. per bushel extra, were submitted by the Longwood Branch of the Agricultural Bureau, with the question as to whether the feeding value of the lighter colored sample was worth the

extra 2d. per bushel. Reply—The following analytical data has been supplied by the Director of Chemistry:—

|                          | No. 1 Sample.<br>Per cent. | No. 2 Sample.<br>Per cent. |
|--------------------------|----------------------------|----------------------------|
| Moisture . . . . .       | 8.61                       | 8.62                       |
| Ash . . . . .            | 1.81                       | 2.34                       |
| Protein . . . . .        | 12.19                      | 14.15                      |
| Fats . . . . .           | 1.98                       | 3.87                       |
| Starchy matter . . . . . | 73.46                      | 65.78                      |
| Fibre . . . . .          | 1.95                       | 5.24                       |

The lighter color is probably due to a higher proportion of flour in No. 1 than in No. 2, and hence the higher proportion of starchy matter, 73.46 per cent. in No. 1 and 65.78 per cent. only in No. 2. On the other hand, the higher proportion of husk in No. 2 leads to a darker color and a higher proportion of protein, namely, 14.15 per cent. in No. 2 and 12.19 per cent. only in No. 1.

For definite comparison it is necessary to determine what is known as the starch equivalent for each sample, that is to say, the number of pounds of starch to which 100lbs. of each sample corresponds as a foodstuff. I calculate the starch equivalent to be 57½ for sample No. 1 and 57½ for sample No. 2. It follows that, from the standpoint of feeding value, there is not much to choose between the two, particularly at present current prices.

If sample No. 2 were worth 1s. a bushel, No. 1 would not be worth more than 1/20th of a penny extra, and No. 2 would have to reach the fantastic figure of 38s. 2d. a bushel before No. 1 could be worth as feeding material 2d. a bushel more than No. 2.

---

[Replies supplied by Mr. W. J. SPAFFORD, Deputy Director of Agriculture.]

---

### Lucerne.

Questions submitted by a correspondent at Currency Creek:—

1. When establishing lucerne, in August, I applied a bag of 45 per cent. superphosphate per acre; would it have been better if I had used stable or pig manure? Reply—Superphosphate is the best fertiliser to use when establishing a stand of lucerne. Unless farmyard manure is well rotted before application, or is ploughed in before bare fallowing, so many weeds germinate at the same time as the lucerne that the crop suffers. Now that the lucerne crop has been established, farmyard manure can be applied with advantage in late July or August, and weeds which do appear will not interfere with the lucerne plants.

2. Would it be advisable to manure the lucerne crop again? Reply—Lucerne should be manured every year, and as it is also advisable to cultivate the lucerne crop every year, the two operations can be carried out at the same time. In July each year the soil should be thoroughly stirred with a cultivator with very narrow shares, and then 2cwts. superphosphate drilled in to the acre. If the land is sandy, heavily weighted harrows will do all the cultivation necessary. If farmyard manure of any kind is available, it can be applied before the cultivation.

3. What is the best way to eradicate lucerne flea? Reply—We have had success by feeding down the affected crop, then spraying with about 80galls. per acre of a mixture of 10lbs. arsenate of lead, 2 quarts of nicotine arsenate, 500galls. of water.

4. Can you recommend a sprinkler that will water a good distance under fairly low pressure? Reply—Nearly all sprinklers do better work when there is a fair pressure of water, and if a big throw is desired high pressure is essential, still the Rain-maker type of sprinkler throws the water a fair distance, even when the pressure is fairly low.

**Nitrate of Soda for Top Dressing.**

Does top dressing with nitrate of soda in dry, hot, windy weather have any effect in burning off crops? (Weavers Agricultural Bureau.) Reply—Nitrate of soda will burn the foliage of cereal crops if allowed to remain in contact with it for any length of time, particularly if some moisture collects on the foliage. If the nitrate of soda broadcasted on to the crops was dissolved in the moisture deposited from dews, it would probably burn the foliage. Nevertheless, no damage to crops is to be expected because of top dressing with nitrate of soda in the ordinary course of events, and even in exceptional circumstances the harm done to the foliage should only be very slight.

**Salt Bush.**

Can seed be obtained of the salt bush growing at the Waite Research Institute, and can it be grown in this district? (Wallala Agricultural Bureau.) Reply—The salt bush being grown at the Waite Research Institute is *Atriplex semibacatum*, and seed of this kind can be purchased from most of the large seedsmen. Judged by the way it grows and has spread at the Minnipa Experimental Farm, it should do fairly well in the Wallala district.

**Free Gallipoli Wheat.**

Is Free Gallipoli wheat suitable for this district? (Wallala Agricultural Bureau.) Reply—Free Gallipoli may do fairly well in the Wallala district, but it is a wheat more suited to heavy rainfall and good agricultural conditions.

**Oats for Feed and Hay.**

What is the best class of oats to sow to feed off and then leave for hay? (Palabie Agricultural Bureau.) Reply—It is not reasonable to expect oats to give a hay crop after having been heavily grazed, except in the very best of agricultural conditions, and it is a pure gamble to try it in most of our mallee districts. If this method of hay-growing is to be chanced, then there is more chance of success with early varieties of oats, such as Early Burt, Palestine, or Bathurst Early.

***Poa aquatica*.**

Possibilities of *Poa aquatica* (water meadow grass) as a fodder grass? (F. B. F., Jamestown.) Reply—*Poa aquatica* appears to have done remarkably well in some parts of Australia, but there seems to be something about our climate or the quality of the waters of our lagoons and low-lying flats which does not favor the grass. Quite a lot of people have tried the grass in various parts of the State, but I know of no one who has had full success. There is more chance of success with Strawberry Clover than with *Poa aquatica* on low-lying soils frequently covered by water.

**Field Peas for the South-East.**

Is there a variety of field pea suitable for the black soil of the South-East (similar to Penola soil) which could be planted in late October? (Coonawarra Agricultural Bureau.) Reply—In the pea-growing districts of this State, the seeding is done about June, and we have no varieties of field peas sufficiently early maturing to permit of such late seeding as October, even in the South-East. The Brunswick White, which is a good deal earlier than the other common kinds of field peas, can be sown at a later date than the others, but in all probability October seeding would prove quite unsuitable in most seasons.

**Grey and Blue Peas.**

Market quotations show a difference in price for grey and blue peas. What is the difference? Reply—The difference in price between grey and blue peas does not appear to always favor the one kind, and seems to depend upon the supply of each

## SHELL PRODUCTS -for' the man on the land

CROSS POWER KEROSENE

GOLDEN SHELL OIL

AGRICULTURAL OILS

Each Product is as near perfection for its specific purpose as is possible for modern chemical science to attain. \* \* \*

### Cross Power Kerosene

The outstanding tractor fuel on the Australian market. Provides maximum power, economy and efficiency.

### Golden Shell Oil

Ensures easier working, and prolongs the life of the tractor.

### Agricultural Oils

As good as Shell Motor Oil. A grade for every type of farm machine.

### Stock-marking Pencils

Three distinctive colours—Red, Blue and Black. Sold in metal containers—do not break or crumble.

### Wool-marking Oils

In four distinctive and fadeless colours—Red, Yellow, Blue and Black. Harmless to wool and skin, and disappear completely in the scour.

### Defiance Blowfly Oil

Prevents blowfly strike in sheep, and has valuable antiseptic and healing properties.

STOCK-MARKING PENCILS

10000

variety on hand at any given time. The grey peas are locally grown, but the blue peas come from Tasmania, and as the supply and quality vary a good deal, according to the season, so does the price.

#### **Sodium for Control of Mustard and Dock.**

Would sodium chlorate be likely to prove effective in checking mustard and dock, and what is the price commercially of sodium chlorate? (Coonawarra Agricultural Bureau.) Reply—Sodium chlorate would kill both mustard and dock if sufficient quantity of a 5 per cent. solution be sprayed on the plants to thoroughly wet them. As this material will burn the green growth of all plants, the spraying must be done when the land is out of crop, and it must be remembered that it leaves the soil sterile for some little time after spraying. Crude sodium chlorate is about £45 a ton, and can be purchased from Hardie Trading Pty. Ltd., Currie Street, and Cresco Fertilizers Ltd., North Terrace.

#### **Red Rust.**

Is a fungus classed as a disease? (Marama Agricultural Bureau.) Reply—A reasonable definition of "disease," as taken from the dictionary, is—"a derangement in the structure or the function of any organ belonging to a vegetable, or an animal organism, or to any organised body." When such a derangement is caused by a parasitic fungus the disease is then known as a fungus disease. Although some fungi can cause diseases, because they are parasitic or living organisms, many of them have no connection with diseases, as they are not parasitic and get much of their sustenance from dead organic matter.

Is rust a disease or fungus? Reply—Red rust is a fungus disease, *i.e.*, it is a fungus which grows on plants as a parasite, taking all of its food requirements from the host plant on which it lives.

Is rust caused by humid conditions followed by heat, and does it do less damage in thin crops? Reply—Red rust is a fungus growth on the plants, which develops very rapidly in muggy weather, *i.e.*, in warm, moist weather conditions, and does most damage in thick, luxuriant crops which have grown very quickly. Light, open crops, which dry out readily and admit moving air easily, are rarely badly affected by the disease.

[Reply by R. C. SCOTT, Superintendent Experimental Work.]

---

#### **Irrigation of Lucerne.**

"W. A. R.," Lyndoch: "I have half an acre of deep sandy soil; water is laid on 5 chains away. If I could get two cuts lucerne by average rain, would it pay to irrigate to get a third or fourth cut, with water at 1s. per thousand gallons excess rate." Reply—With water at 1s. per thousand this is not likely to prove directly profitable. However, it must be remembered that supplementing the ordinary ration with a proportion of green lucerne makes a considerable difference to the milk yield of your cows. To get maximum returns the lucerne must be watered between each cut at the rate of at least 6ins. of water per acre. In many irrigation settlements an acre-foot of water is supplied. An application of 6ins. of water equals 134,400galls. per acre; with green lucerne valued at £1 per ton this means that each cut must yield 6 tons 14cwt. per acre to pay for water at 1s. per thousand gallons. Naturally the quantity of water utilised would be reduced by the amount of rain recorded. Lucerne will give fair returns with much less water, but unless it is available at cheap rates, it is not advisable to attempt to irrigate a plot of any size. With average summer rainfall, you should secure two fair cuts, and it is suggested that if half an acre is planted, you irrigate, say, half this area. The irrigated portion would yield four cuts, at a cost of about £4 for water. The green stuff obtained would be of great benefit to your cows, and in my opinion, the expense of irrigation would be justified. However, the area so treated should not be large. In the class of soil mentioned, namely, sand overlying clay at a depth of about 3ft., it would be best to irrigate by means of the sprinkler.

**HORTICULTURAL INQUIRIES.**

[Replies supplied by Mr. G. QUINN, Chief Horticultural Instructor.]

**Budding Fruit Trees.**

Is it advisable to bud apricots and peaches on almond trees? (A. J. M., Cherry Gardens). Reply—The almond is only desirable as a stock for peaches and apricots when certain soil and drought conditions have to be overcome. Soils which are too highly calcareous or dry for peach or apricot roots will not seriously injure the almond. Generally speaking, unless exceptional advantages are offered for the fruit grown in the locality, the almond is not a commercial success as a stock for these fruit trees.

**Prevention of Disease in Potatoes.**

“W. G. E.,” Kalangadoo, asks for details of treatment to prevent disease in potatoes. Reply—In the first place, without seeing a potato affected by the particular disease you have to contend with, I am at a disadvantage in offering any advice owing to the great number of diseases in potatoes, each of which is due to an entirely different organism or cause.

As you mention formalin, I may say that compound has been used in solution as a dip for seed potatoes affected by “scab” on the skin—“scab” said to be caused by a fungus (*Actinomyces* sp.).

If, therefore, the disease you have in mind is “scab,” the formalin treatment consists of dissolving 1lb. of commercial formalin in 30galls. of water. Place the seed tubers in a loose, open-woven sack and steep them for a couple of hours before cutting if they are not whole seed. Anyway, if cut or not, they are allowed to dry off before planting. A very deadly poison, commonly known as corrosive sublimate, used similarly at the rate of 1oz. in 6galls. of water has proved very effective. It is dissolved in a little hot water and then poured into the 6galls., which are placed in a wooden

vessel, as this chemical attacks iron containers. Care must be taken with this reagent as it is extremely poisonous to man and animals.

In case I have not located the disease you desire to prevent, the best course would be to send me an infected tuber or some diseased haulms to enable identification being made.

---

### **The "Off Year."**

Commenting on the established fact that many fruit trees bear a big crop in one year and a small crop in the next, and that two good years rarely follow one another, Mr. Chas. H. Beaumont (District Horticultural Instructor) stated that he has noticed that some orchards bear well on the general "off year" and bear only a few fruits on the general "big year"; indeed, individual trees in the orchards also show this peculiarity, so that climatic conditions and insect interference cannot be held to have any special effect; nor can it be attributed to the stocks, because at least 90 per cent. of the stocks used are similar in every respect. Nearly every orchardist has his own special idea on the matter, and many are trying to demonstrate their theories and to overcome the trouble to some extent.

Last year there was a general big crop—bigger than usual—and the reason that it was bigger was probably due to the fact that the trees were weaker owing to the lack of winter rains. Weak trees usually set heavier crops than vigorous trees; they aim to reproduce themselves before passing out, and so set a big crop of what is mostly inferior fruit, inferior in size, inferior in quality and in color; hence, artificially weakening trees are not a good commercial proposition.

Last year some of the growers in his district decided to prevent a number of trees from bearing by removing the blossoms. One grower actually cut off the flowers of several fair-sized trees; others spoiled all chance of pollination by burning the flowers with a spray of lime-sulphur strong enough for the purpose; others, again, pulled off the fruit when it was big enough to handle easily, and in one neglected orchard all the fruit was knocked off so that the owner might be relieved from the necessity of spraying to control codlin moth. In all these instances a crop has set this year; whilst other trees near by, not so treated, are bare or nearly so. Whether the procedure will alter the habit of the tree permanently remains to be seen.

He has examined trees which had been treated with fertilisers in the hope that a second continuing crop would result, but has not found this satisfactory as a whole, with the exception where the trees so treated were also supplied with water at the critical time.

Usually when trees are bearing a very heavy crop, there is a deficiency of foliage and of a growth of new wood. There was a wonderful show of blossom this year on most of the trees which bore heavily last year, but it was noticeable on close examination that the flowers were not perfectly formed and there was consequently no pollination.

In a number of orchards it is a practice to grow vegetables between the trees on portions selected as suitable; this means the use of fertilisers and also the use of water. The trees in these portions bear a crop of fruit every year. One grower used a patch of ground for some years to raise onion seedlings; there were nine apple trees in the patch, and they bore continuously. He then began to raise the onion plants elsewhere and did not water the trees and they failed to bear; last year they had a big crop and this year the crop is small.

With apple trees particularly it is necessary that they should bear the crop and form buds for the coming year, so that growing new wood and a generous foliage is a necessity for the wellbeing of the tree, if it is to mature the buds so formed. The control of the quantity of fruit on the tree and the supply of sufficient moisture seem to be necessary if regular bearing is desired.

Mr. Beaumont has suggested to several growers that they should water some of the trees as soon as the crop is off, and, if the winter rain is late, continue to irrigate them. If heavy rains come later it would do no harm, if the orchard is reasonably drained. It should tend to lengthen the growing period and thus stimulate the trees and help to mature the buds.

### VETERINARY INQUIRIES.

[Replies supplied by Veterinary Officers of the Stock and Brands Department.]

"M. M.," Jamestown, has horse with a board-like swelling along one side of belly. Reply—The symptoms suggest that an abscess is in course of development or that the animal has a wound somewhere under the belly or forearm. An abscess may be caused by entrance of a thorn or splinter. For treatment, it is advised that a careful examination be made for a wound or presence of splinters, thorns, &c. Bathe the swelling for five to 10 minutes at a time three or four times a day with hot water in which a little disinfectant, such as lysol, has been added. The water should be kept at an even temperature by adding more hot water from time to time. If swelling "points," it should be opened at lowest part with a clean, sharp penknife and then syringed out with lysol solution (one tablespoonful to one pint of water).

"E. B. P.," Murraytown, reports gelding 14 years old passing water tinged with blood. Lips swollen and low in condition. Reply—As the passage of blood in the urine may occur in quite a number of different diseases of the urinary organs, it is impossible to diagnose the case from the particulars given. It would appear to be some chronic and probably incurable condition, and in view of the age and condition of the animal, destruction would be the best course to take. If the owner would care to subsequently send us down the animal's kidneys and bladder (preserved in weak formalin solution), we would have an examination of these organs made to try to determine for his and our information the exact nature of the trouble. The package containing the organs should be addressed to Chief Inspector of Stock, Stock and Brands Department, Adelaide, and should be accompanied by a letter advising its dispatch.

Secretary, Agricultural Bureau, Blackheath, asks:—(1) Information re hand serving ewes. (2) A reliable means of "bringing on" the ewes quickly. (3) Is there any advantage in allowing the ram to serve more than once? (4) A suitable ration for a ram. Replies—(1) The usual practice is to yard the ewes daily and turn in amongst them "teaser" rams guarded with bagging to prevent service. As the ewes in season are discovered by this means, they are caught and placed in a separate yard till all are ready for service or sufficient for the day for the stud rams are available are secured. The ram and ewe to be mated are then placed together, and when effective service is assured the ewe is branded and turned into the service paddock. (2) "Flushing" the ewe on green feed (preferably) or grain for two or three weeks prior to the desired date of breeding will bring them to the ram in briefer periods and tends to materially increase the percentage of lambs. (3) No, one service should suffice. (4) Feed what hay (fine, short oaten hay for preference) they will eat, together with a little green lucerne if available. In addition, feed daily 6ozs. to 8ozs. of mixed oats and peas with a little bran. The grain should be crushed or soaked before mixing. If any signs of scouring arise, cut out the lucerne and bran.

"Mrs. F. W. A.," Pinnaroo, reports pigs three months old, in good condition, lost use of hindquarters. Pigs being fed on wheat, charcoal, bonemeal, pollard, and skim milk. Reply—Continue to feed on the ration you are at present using, and give each pig one teaspoonful of freshly slaked lime daily mixed in with the trough food. Also allow them to have daily exposure to sunlight and give one or two teaspoonfuls of cod liver oil per pig per day.

"G. H. H.," Tintinara, reports cow calved five weeks ago, milking fairly well, holds head straight out, eyes have glassy appearance. Reply—From information given it is difficult to make a diagnosis. However, it is possible that the condition may be a form

of milk fever. If the cow is no better it is suggested that she be stripped out and pumped up with air as for milk fever. Further, provided the cow can drink properly, give the following drench:—Epsom salts, 1½ lbs.; ginger, four tablespoonfuls; treacle, one cupful; warm water, two pints. Subsequently give a teaspoonful of pulv. nux vomica night and morning for seven to 10 days. To give, mix with treacle and smear on back of tongue.

“E. H. R.,” Wudinna, reports pig (boar) born without a back passage. Reply—Unless surgical treatment is given the animal will before very long sicken and die. The surgical measure to be adopted depends on the exact nature of the obstruction. If the occlusion of the passage is merely due to the presence of skin over the exit of the bowel (in which case the presence of faeces or dung in the bowel can readily be felt with the fingers), all that is necessary is to incise the skin with a pair of scissors and subsequently smear the edges of the wound with a mild antiseptic ointment to prevent reunion of the cut edges. If, however, the occlusion extends more deeply and involves the hinder portion of the bowel as well, it will be necessary, after incising the skin, to introduce the oiled finger and try to break down the adhesion of the bowel wall so as to make a passage. Enemas must be used for some days subsequently to prevent the walls of the bowel from growing together again.

“L. W. C.,” Marama, reports (1) horse losing condition although receiving good feed, and (2) horse with small swelling on outside of hock. Replies—(1) *Re Horse falling away*—The animal's teeth require attention. Further, starve him for 16 to 24 hours and give him a drench of raw linseed oil, 1½ pints; turpentine, four tablespoonfuls. Subsequently, supplement his grazing by feeding on an allowance of good chaff and bran daily and give in the damped feed a tablespoonful of Fowler's solution of arsenic night and morning each day for a fortnight. (2) *Re Horse with swollen hock*—The condition is probably bog spavin. The animal should be given a dose of physic and a little one in eight red iodide of mercury blister rubbed in over swelling on inside and outside of hock joint (do not put any in front of the hock where it bends). The animal should then be turned out for two or three months' spell.

“A. J. M.,” Cherry Gardens, reports sow eating young. She was fed on potatoes, swedes, and mangolds boiled and mixed with bran and pollard. Reply—The trouble has been caused through feeding the sow on an unbalanced ration, woefully deficient in protein and minerals. To prevent this happening, the rations of pregnant sows should contain, in addition to cereals and other carbonaceous feeds, a regular, liberal allowance of skim milk or up to 10 per cent. of meat meal; also, if possible, a limited daily allowance of chopped green feed, such as lucerne, should be fed and the following mineral mixture provided:—Common salt, one part; sweet ground bonemeal, two parts. This can either be put out in a box in a handy position in the sty or run so that the sows can feed from it at will, or it can be fed mixed in with the trough feed at the rate of 1 oz. per sow per day.

“C. T. A.,” Kongorong, reports death of lambs. Walk around in a circle until exhausted. Eyes inflamed, head held on one side, and the body trembles. Lung worms are also causing trouble. Reply—In the absence of further inquiry, it is impossible to state definitely the cause of the trouble, though from the particulars you supply re symptoms, it seems to be of a dietetic nature. It may be due to the ingestion of some plant, or again, it may be the outcome of some mineral deficiency in the feed. All one can suggest from present information is a change of the affected flock to fresh pastures and the supplying the animals with a lick composed of either (a) common salt and sweet ground bonemeal in equal proportions or (b) common salt, one part; ground rock phosphate, one to two parts; molasses, 10 per cent. added. *Re Lung worms*—There is as yet no really satisfactory method of treatment for these parasites. The following

preparation for intra-tracheal injection (if it can be carried out) is recommended:—Oil of turpentine, 20 drops; oil of creosote, 10 drops; chloroform, 10 drops; olive oil, one teaspoonful. This is a dose for a full grown sheep and may be decreased by one-third for lambs. The injection is given slowly, direct into the windpipe, about half way down the neck, using a hypodermic syringe. Severe coughing generally occurs after its administration. Three or four injections are necessary at daily intervals.

“E. H. P.,” Rockleigh, asks is there any method of causing a sheep to “throw up” anything harmful which it might have swallowed? Reply—There is no medicine which can be given to ruminating animals, such as sheep or cattle, which will induce vomiting. The specific antidote for arsenical poisoning is to mix liquor ferri per-chloride with carbonate of soda, dissolved in water, in the proportions of 2ozs. or 3ozs. of the former to one of the latter. The resulting precipitate should be filtered off through a piece of linen or a pocket handkerchief and given straight away as a drench mixed in warm water. It may be given *ad lib.* in repeated doses. Oil, milk, white of egg, lime water and fluid magnesia are all serviceable antidotes which can also be used.

## METTER'S “NUOIL” DOUBLE GEARED SELF-OILING WINDMILLS.

IN SIZES FROM 8ft. TO 14ft. WHEEL.

The strongest, best lubricated, best designed, and best governed.

Pump more water on a lighter breeze.

No spring on automatic oiling system to break, and no sheet-metal oil conveyors to wear out.

Gained First Prize and Silver Medal Adelaide Show, 1922, 1923, 1924, 1925, 1926, and 1930 (no entry 1928-29).

Also Gold Medal at the All-Australian Exhibition, 1930.

A reliable and useful investment, and the popular choice of experienced pastoralists, farmers, and others.

### METTER'S 5ft. “MINOR” WINDMILLS.

Most efficient for pumping water from shallow depths.

MILL ONLY, £9 15/0; on 15ft. G.I. TOWER, £15 15/0; on 20ft. TOWER, £17 17/6.

## THE BRITISH MARKET FOR AUSTRALIAN BARLEY.

---

An important announcement on the marketing of Australian barley in Great Britain has been furnished to the Agent-General for South Australia by a representative of a firm of brewers operating in a large business way in London. The statement made by this gentleman—who is fully conversant with the details of the British market for Australian barley—arose from a conversation with the Agent-General on the falling off in the quality of our barley and the damage which was resulting to Australia in consequence.

The full text of the statement is as follows:—

“The total consumption in brewing is roughly 4,000,000 quarters of barley, say 800,000 tons. To this must be added a considerable quantity for distilling and also the production of foods, such as malt extract, which, however, are not material. Of this, something like one quarter, say 200,000 tons, is imported, but this varies from year to year to some extent according to price and quality. Foreign barley, however, is primarily used to correct the deficiencies of English barley, and a considerable amount would be used whatever the price. On the other hand, if it is exceedingly cheap, the consumption tends to increase.

There are two kinds of barley—the two-rowed barley such as is grown in Europe, and the six-rowed barley, the long thin type, which is grown in California, Africa, etc. There is a regular supply of barley from California, and the market is arranged on well-defined principles, and the majority of six-rowed barley comes from that district.

There is a demand for two-rowed barley from sunny climes, and this would be larger if a regular supply were obtainable. Substantial supplies of two-rowed barleys come to this country from Moravia, Czecho-Slovakia, &c. Both two-rowed and six-rowed barleys are grown in Australia, but the results have not been satisfactory owing to fluctuations of quality, irregular supplies, &c. The criticism I have heard of Australian six-rowed barleys is that they frequently contain undue proportions of nitrogen, and the growers do not seem able to control this.

A difficulty to be got over is the fact that Australia harvests its crop round about January, and it arrives in this country too late for that malting season and has to be kept several months before it can be malted. On the other hand, Californian barley is harvested round about June, and arrives here before or during the malting season.

I recently had a conversation with a man who interested himself very much in Australian barley a few years ago. His view was that it would be difficult, if not impossible, for Australia to compete with California in matters of price (of course, a preferential tariff might alter this), especially when the difficulty of the harvest season is taken into account. But he saw no reason why there should not be a large demand for Australian barley of the two-rowed chevalier type if it were properly grown from the right seed, harvested, and delivered. His experience proves that it is futile discussing any substantial business with Australia owing to the complete inability of the Australian business man to deliver up to sample. He told me that he had succeeded in selling 3,000 quarters to a noted English brewery, that he had impressed on the vendors that if it was to be the father of future orders it must be up to sample, that the agents here had shown him a cable from the vendors' agents in Australia saying that every bit was equal or superior to the sale sample, but that when the delivery arrived he was unable to find a single sack that was up to description. The brewers

(PATON)

threw up the consignment and my friend lost £3,000. I have confidence in my friend's report of this particular transaction, and the general impression on the market is something of a similar description.

The general conclusion, therefore, is this: that Australia can grow barley which will compete with Californian in quality, but that price and date of harvesting present difficulties. That Australia can produce two-rowed barley which would command a sale amongst the best brewers in this country if deliveries can be relied upon. That this would be the most promising field for Australian produce as the price paid for two-rowed barley is considerably more generous than for six-rowed and is free from the formidable competition of Californian. That the market is very much prejudiced against Australian produce owing to the difficulty of getting delivery, and that if a revival of this market is contemplated, it would be necessary first to organise proper machinery for shipment and then to convince users in this country that this machinery was adequate.

From the way my friend talked and what I have heard in other directions, some financial guarantee would be required. It may very likely be that the natural conditions make it more difficult for the Australian shipper to deliver the goods than from other countries of supply. I cannot say how this may be, but the impression here is that Australia is simply indifferent.

I have written rather bluntly, but thought it better to do so as you may take it this represents the sort of feeling amongst purchasers of barley towards the Australian produce. My opinion is that it would be quite practicable to develop a large trade if only Australia can deliver the goods, and this will be your real problem."

Mr. T. W. Rosenfeldt's (Greenock) winning crop, Centre Crop Competition, 1930.

## NINTH ANNUAL REPORT OF THE TURRETFIELD DEMONSTRATION FARM (1929-30), INCLUDING DE- TAILED ANALYSIS OF MEAN FARMING COSTS (1921-30).

[By ARTHUR J. PERKINS, Director of Agriculture.]

(Continued from page 491).

### COST OF GROWING CEREAL HAY AT TURRETFIELD.

#### (a) CEREAL HAY SOWN ON BARE FALLOW.

It should be observed here that between 1921 and 1925 Cereal Hay was Turretfield's main crop. The progressive displacement of light horses by motor cars, the electrification of the tramway system, &c., tended to render the growing of Hay for sale purposes more or less unprofitable; hence, between 1925 and the 1928-29 season, Wheat harvested for grain displaced Hay at Turretfield, no more hay being cut than was required for home consumption. The great bulk of this Hay was derived from headlands and roadways through the standing crops, and it follows that our handling costs have been heavier than those usually incurred by the normal Haygrower who is able to deal with large, continuous areas. Our costs, however, would not have been greater than those usually incurred by the average farmer, who, like us, cuts Hay for home consumption only.

In the 1929-30 season, owing to prospective low Wheat prices and the general shortage of local Hay supplies, a larger area than usual was cut for Hay at Turretfield, portion of which it was proposed to sell, although, unfortunately, the opportunity of doing so was missed.

In Table XVII, the costs incurred for growing Hay on Bare Fallow in 1929-30 have been indicated, together with corresponding mean figures for the 1922-29 and 1922-30 periods.

**IF YOU HAVE THE WHEAT  
WE HAVE THE TRUCK TO LOAD IT.**

### **CAMPBELL'S PATENT ONE-MAN ELEVATING TRUCK**

with which one man can pick up EASILY full bags of Grain, Super, Boxes, &c., wheel them to a lorry or platform, and by lifting handle of truck platform can load the lorry without any assistance. . . .

Further, you don't have to bring the bag to the lifter—nor do you have to pull the lifter with the bag to the required position. . . .

**THE BAG IS ON THE TRUCK WHEELS (15" x 2½") READY FOR WHEELING,

| Mean Yields per Acre .....                             | Tons.<br>1.79     |             |                  | Bush.<br>19.46         |                |                  |

The above statements show that, whereas over a period of eight successive years it has cost at Turretfield £4 14s. 8d. to grow and harvest a 19½ bush. crop of Wheat, corresponding expenditure over the same period for a 1½ ton crop of Hay has been at the mean rate of £5 6s. 5d. per acre. In other words, over this period of years the mean cost of growing and harvesting a Hay crop has been 11s. 9d. an acre higher than corresponding expenditure for a Wheat Crop harvested for grain. And unfortunately at the present time the plight of the Haygrower is even worse than that of the Wheatgrower. With Wheat at 2s. a bushel the loss to the grower on a 19½ bush. crop would be represented by £2 15s. 9d. per acre, whereas the loss to the Haygrower, with Hay at 20s. a ton, would, for a 1½ ton crop, be represented by £3 10s. 7d. per acre.

Harvesting Costs—binding, stoking, carting, and stacking—are mainly responsible for the higher relative costs of Haygrowing, namely, in the aggregate 29s. 10d. per

acre as against 16s. 9d. for corresponding grain harvest costs, representing an increase of 78.1 per cent. In this increase in harvesting costs Labor is the chief beneficiary, absorbing 14s. 9d. per acre for hay as against 3s. 8d. for a corresponding grain crop, or an increase of 302.3 per cent.

It is, of course, true that in Haygrowing districts farmers often seek to avoid portion of Hay harvesting costs by selling their hay in the stook, but of late not even this policy has proved altogether remunerative. I shall endeavor to set out the position from the latter viewpoint with the aid of available Turretfield data.

The costs of carting and stacking hay at Turretfield over the past eight years have been as follows:—

| Seasons.            | Hay<br>Carted and<br>Stacked. | Total Costs. |    |    | Costs<br>per<br>Ton. |
|---------------------|-------------------------------|--------------|----|----|----------------------|
|                     | Tons.                         | £            | s. | d. | s. d.                |
| 1922-23 .....       | 489-30                        | 144          | 16 | 8  | 5 11                 |
| 1923-24 .....       | 56-50                         | 32           | 0  | 9  | 11 4                 |
| 1924-25 .....       | 230-00                        | 93           | 12 | 6  | 8 2                  |
| 1925-26 .....       | 219-50                        | 118          | 12 | 11 | 10 10                |
| 1926-27 .....       | 122-50                        | 69           | 7  | 1  | 11 4                 |
| 1927-28 .....       | 175-00                        | 85           | 8  | 8  | 9 9                  |
| 1928-29 .....       | 77-00                         | 43           | 10 | 9  | 11 4                 |
| 1929-30 .....       | 317-00                        | 170          | 8  | 10 | 10 9                 |
| 1922-30 Means ..... | 210-85                        | 94           | 14 | 9  | 9 0                  |

From the above, it follows that the mean costs of carting and stacking Hay at Turretfield have been represented by 9s. a ton or for a 1.79 ton harvest by 16s. 1d. per acre. Hence, mean costs of growing Hay and stooking it in the field would be reduced to 50s. 6d. a ton, or 90s. 4d. an acre for a 1.79 ton harvest; that is to say, 4s. 4d. per acre less than corresponding costs for growing and harvesting a 19½bush. Wheat Crop. But even this reduced figure (£4 10s. 4d. per acre) leaves a deficit of £2 14s. 6d. per acre for a 1.79 ton crop sold at £1 a ton in the stook, and farmers are known to have accepted 15s. in the present season.

It can be admitted, however, that for a farmer with a large family, Haygrowing presents certain definite advantages over Wheatgrowing when yields and current prices can be made to balance costs of production. It has already been pointed out that a farmer harvesting a 19½bush. Wheat crop from 300 acres and balancing costs of production by sales at 4s. 10d. would have earned £355 in the way of wages for himself and family, together with adequate interest on Capital invested. Similarly, a farmer who cuts and stacks 300 acres of Cereal Hay going 1½ tons to the acre, and who is fortunate enough to balance costs by sales at 59s. 6d. per ton, would have earned £526 in the way of wages for himself and family, in addition to adequate interest on Capital invested. Hence, from this viewpoint, when receipts can be made to balance expenditure, the advantage is decidedly with the Haygrower blessed with a large family.

It is true that the costs of Production given for both Wheat and Hay are "inclusive" costs, i.e., they include not only out-of-pocket expenditure, but in addition book entries, which some may consider out of place. Reference to Statement C will show that Interest on Land and Improvements, Interest on Working Capital, and Depreciation on Improvements and Plant—all of which are mere book entries for those who are fortunate enough to be free from debt—aggregate 1s. 8d. per Bushel for Wheat and 18s. 7d. a ton for Hay. If we deduct these items which do not involve out-of-pocket expenditure for those who are free from debt our costs per unit would be reduced to 3s. 2d. per bushel for Wheat and 40s. 11d. per ton for Hay in the stack, or 31s. 11d. for Hay in the stook. But unfortunately prices offering to-day for neither Wheat nor Hay will balance these revised estimates of Costs. If, on the other hand, in addition to these deductions, we assume that the farmer's labor can go for nothing—18s. 10d. per ton

of Hay and 1s. 2d. per bushel of Wheat—our costs would finally be brought to closer approximation of present-day prices, namely, 2s. a bushel for Wheat and 22s. 1d. per ton of Hay.

*Working Hours.*—I have shown below in summary the mean number of working hours absorbed in growing and harvesting one acre of Hay in contrast with corresponding figures for Wheat:—

|                         | Hay.   |       |                      |        | Wheat. |       |                      |        |
|-------------------------|--------|-------|----------------------|--------|--------|-------|----------------------|--------|
|                         | Costs. |       | Corresponding Hours. |        | Costs. |       | Corresponding Hours. |        |
|                         | s. d.  | s. d. | Hours.               | Hours. | s. d.  | s. d. | Hours.               | Hours. |

| Spring Tillage.....     | 0      | 2     |                      | 0-11   | 0      | 1     |                      | 0-06   |
| Harvest Operations ..   | 14     | 9     |                      | 10-92  | 3      | 10    |                      | 2-85   |
| General Expenses ....   | 7      | 6     |                      | 5-52   | 6      | 10    |                      | 5-02   |
|                         |        | 29 1  |                      | 21-51  |        | 18 2  |                      | 13-43  |
| Indirect Labor .....    |        | 6 0   |                      | 4-43   |        | 5 6   |                      | 4-07   |
| Totals .....            |        | 35 1  |                      | 25-94  |        | 23 8  |                      | 17-50  |

Number of 9½-hour days ..... 2.73 days

1.84 days

It follows that, whereas at Turretfield one acre of Wheat sown on Bare Fallow has absorbed 17½ hours of labor, or 1.84 working days, the corresponding figures for one acre of Hay in the stack has been 26 hours, or 2¾ working days. The heavy requirements of Hay at harvest time—10.92 hours per acre—are in striking contrast with those of Wheat—2.85 hours per acre.

(b) CEREAL HAY SOWN ON STUBBLE GROUND.

Small areas of stubble land sown to Cereals (usually Oats) are generally cut for Hay at Turretfield. Expenditure incurred in 1929-30 on 45.08 acres, giving 0.57 tons to the acre, has been analysed in Table XIX. in contrast with Means of preceding seasons.

# GRUBBING

## IS A ONE MAN JOB

FOR STUMPS LARGE OR SMALL, GREEN OR DRY, SHORT OR HEAD-HIGH. THE ENORMOUS POWER OF A

## MONKEY GRUBBER

EASILY ACCOMPLISHES THE TASK.

Removing the most stubborn obstacles cleanly, with most roots intact. Easy to handle, simple to operate, expeditious—its only need, regular oiling. The Standard equipment will clean up everything over 1½ acres from one anchorage.

Each part designed for simplicity, easy handling, and long trouble-free service.

| Mean Yields per Acre .....                             | Tons.<br>1.31         |          |             | Tons.<br>1.79             |          |             |

The position, therefore, is that, whilst the mean costs of Cereal Hay grown on Stubble Land were £3 17s. 10d. per acre, corresponding mean costs of Cereal Hay grown on Bare Fallow were £5 6s. 5d. per acre; on the other, mean costs per ton were exactly the same, namely, 59s. 6d. This is to be accounted for by the fact that the mean yield of Hay grown on Bare Fallow was about one-half a ton better than that of Hay grown on Stubbles. The above statements show that the main increases in costs of Bare Fallow Hay arise from more costly tillage operations and 18 months' rent instead of nine, representing in the aggregate 31s. 11d. per acre as against 15s. 1d. for Stubble Hay. Seeding and harvesting operations were also slightly more costly on a per acre basis, but less so on a per ton basis.

*Working Hours.*—I have shown below the mean relative number of hours absorbed by Stubble Hay and Bare Fallow Hay respectively:—

|                       | Stubble Hay. |       |                      |        | Bare Fallow Hay. |       |                      |        |

| Totals.....           | —            | 28    | 9                    | 21·26  | —                | 35    | 1                    | *25·94 |

Number of 9½-hour days      2·24 days per acre.      2·73 days per acre.

In the matter of Labor, therefore, the difference between Stubble Hay and Bare Fallow Hay has been represented by half a working day per acre only.

#### OATS AND BARLEY AS STUBBLE CROPS.

Neither Oats nor Barley have been harvested for grain at Turretfield since 1926-27 season; hence, costs of production indicated in the 1926-27 Report must stand for the present. I have indicated in Table XXI. mean figures for both Oats and Barley under summarised Statements A, B, and C. For closer details I must refer those interested to earlier reports.

TABLE XXI.—*Contrasting Mean Costs of Growing Oats and Barley respectively as Stubble Crops at Turretfield.*

| Totals .....           | 15 4   | —     | 11.34                | —      | 14 11   | —     | 11.03                | —      |

Mean Number of 9½-hour days

1.19 days per acre.

1.16 days per acre.

#### FIELD PEASE GROWN ON STUBBLE LAND AS A FALLOW CROP PRECEDING WHEAT OR HAY.

Within recent years Field Pease have been grown fairly extensively in the Central and Lower North Divisions of the State as a fallow crop immediately preceding Wheat. At Turretfield this practice has been under observation since the 1924-25 season. Unfortunately, a regular succession of unfavorable seasons, coupled with attacks of caterpillars, have hitherto militated against favorable, or even normal, results. Mean yields hitherto secured have been indicated below:—

|                     | Areas Harvested.<br>Acres. | Mean Yields<br>per Acre.<br>Bushels. |
|---------------------|----------------------------|--------------------------------------|
| 1924-25 .....       | 28.40                      | 23.57                                |
| 1925-26 .....       | 37.18                      | 6.42                                 |
| 1926-27 .....       | 35.08                      | 23.92                                |
| 1927-28 .....       | 5.00                       | 3.00                                 |
| 1928-29 .....       | 27.47                      | 3.45                                 |
| 1929-30 .....       | 9.50                       | 3.16                                 |
| 1924-30 Means ..... | 23.77                      | 13.23                                |

It will be observed that over a period of six successive seasons the mean yield per acre has been 13½bush. only, whereas, in normal seasons, 20bush. would be considered a reasonable yield per acre.

In Table XXII. I have summarised 1929-30 Expenditure incurred for Pease in comparison with Mean Costs of preceding seasons.

TABLE XXII.—*Summarising Expenditure Incurred for Pease in 1929-30 in Comparison with Means of Preceding Seasons.*  
 PART I.—*Expenditure on 9½ Acres, 1929-30.*

| 1924-30 .....                     | 19.6    |  | 20.3    |  | 12.5        |  | 47.6          |  | 47.6     |  |              |          |

Unfortunately, like the two preceding seasons, 1929-30 was exceedingly unfavorable to Pease, and yields and costs secured since 1924 give a clear illustration of the unprofitableness of low mean yields per acre. The following statement will serve to illustrate the position:—

|                     | Mean Yields<br>per Acre.<br>Bushels. | Mean Costs. |             |
|---------------------|--------------------------------------|-------------|-------------|
|                     |                                      | Per Acre.   | Per Bushel. |
|                     |                                      | £ s. d.     | s. d.       |

In last year's Report I was able to show on mean results of five successive seasons that the Pease-Wheat rotation had returned an excess of 15s. 11d. per acre above corresponding returns from the Bare Fallow-Wheat rotation. I was able at the time to assume prices of 5s. per bushel for Wheat and 6s. for Pease\*. To-day, with all prices

\* See *Journal of Agriculture*, December, 1929, page 409.

abnormally low, the comparison is no longer possible. On the farm Wheat is not worth more than 2s. a bushel and Pease 3s. 6d. On this basis the Pease-Wheat rotation closes on a Loss of £3 9s. 4d. per acre and the Bare Fallow-Wheat on a Loss of £2 15s. 9d. Obviously, we must await a return of more normal conditions for further discussion of this aspect of the question.

*Working Hours.*—Working hours per acre under Crop have already been indicated for other crops. Corresponding mean figures for Field Pease are indicated below in Table XXIV. in association with corresponding figures for Wheat following Pease:—

TABLE XXIV.—*Summarising Working Hours per Acre for Field Pease in Association with Corresponding Figures for the Succeeding Wheat Crop.*

|                                                                |                     |       | 15 8          | 11-61  |                        | 13 8  | 10-12         |        |
| Indirect Labor .....                                           | —                   | 5 4   | —             | 3-92   | —                      | 3 10  | —             | 2-82   |
| Total inclusive Labor .                                        | —                   | 21 0  | —             | 15-53  | —                      | 17 6  | —             | 12-94  |
| Corresponding number<br>of 9½-hour days per<br>100 acres ..... |                     |       | 163 days.     |        |                        |       | 136 days.     |        |

It will be observed from the above that the Pease-Wheat rotation offers greater scope for useful occupation of family labor than the Bare Fallow-Wheat rotation. On the basis of 100 acres Bare Fallow and 100 acres Wheat, the Bare Fallow-Wheat rotation should provide for 184 days of Labor, or a Labor Income of £118 6s. 8d., assuming receipts to balance inclusive expenditure. On the basis of 100 acres of Pease and 100 acres of Wheat sown on Pea Stubbles, the Pease-Wheat rotation should, on the other hand, make provision for 299 days of Labor, representing a Labor Income of £192 10s., always provided that receipts balanced inclusive expenditure.

Pease, moreover, present the advantage of a relatively short growing period, being sown later than Wheat and harvested earlier, and it follows that from the standpoint of the distribution of Farm Labor over the year they adapt themselves well to regular rotation with Wheat.

#### MINIMUM PRICES PER UNIT AT WHICH AGRICULTURAL PRODUCE CAN BE SOLD UNDER TURRETFIELD CONDITIONS AND LEAVE A PROFIT TO THE GROWER.

It is clear that the minimum prices at which growers in a large State like South Australia are in a position to dispose of their produce without loss cannot be determined definitely from the experiences of a single farm in the State. Hence, it must be understood that figures given below can apply to those farms only that are working under economic, climatic, and soil conditions approximating those of Turretfield. In this connection, four factors may be taken to be of major importance in affecting costs and possible minimum prices leaving a margin of profit, namely:—

- (1) Mean yields per acre; the latter are influenced chiefly by rainfall conditions, soil fertility, and management;
- (2) Land values;
- (3) Mechanical character of the soil, which, according to circumstances, renders tillage operations more or less costly; and
- (4) General ability of the farmer to work his farm at a minimum cost.

I have mentioned these points in order to stress the fact that minimum prices which farmers can afford to accept are not necessarily uniform throughout the State, but must vary from district to district and even from farm to farm. Minimum prices indicated below are derived from Turretfield results extending over eight successive seasons:—

TABLE XXV.—*Summarising what Appear to be Reasonable Prices for Agricultural Produce at Turretfield and on Farms Similarly Situated.*

|                          | Number of Seasons Concerned in Calculations. | Mean Yield per Acre. | Mean Costs of Production. |          | Prices per Bushel or per Ton, Leaving a 10 per cent. Profit to Growers. |
|--------------------------|----------------------------------------------|----------------------|---------------------------|----------|-------------------------------------------------------------------------|
|                          |                                              |                      | Per Acre.                 | Per Ton. |                                                                         |
|                          |                                              | Bushels.             | £ s. d.                   | s. d.    | s. d.                                                                   |
| Wheat (on farm) .....    | 8                                            | 19.46                | 4 14 8                    | 4 10     | 5 4                                                                     |
| Pease (on farm) .....    | 6                                            | 13.23                | 4 0 0                     | 6 1      | 6 8                                                                     |
| Barley (on farm) .....   | 5                                            | 17.26                | 2 12 1                    | 3 0      | 3 4                                                                     |
| Oats (on farm) .....     | 2                                            | 21.22                | 2 15 4                    | 2 7      | 2 10                                                                    |
|                          |                                              | Tons.                |                           |          |                                                                         |
| Hay (in the stook) ..... | 8                                            | 1.79                 | 4 10 4                    | 50 6     | 55 7                                                                    |
| Hay (in the stack) ..... | 8                                            | 1.79                 | 5 6 5                     | 59 6     | 65 5                                                                    |

Figures given in the fourth column of Table XXV. would, if and when realised for saleable produce concerned, remunerate the farmer and his family for Labor performed at the standard rate of Wages, and in addition would make adequate provision for depreciation and interest on Capital invested, provided that the farmer secured mean yields corresponding to those shown in the second column of the Table, but these prices would leave no room for Net Profits. On the other hand, should the farmer be fortunate enough to realise prices shown in the last column of the Table, he would—over and above the benefits already indicated—secure a Net Profit equivalent to 10 per cent. on his Harvest turnover. It remains to be said that the mean yields in excess of those shown in the second column of the Table would, at prices indicated, imply proportionally higher Net Profits, whilst mean yields below those indicated would at corresponding prices imply insufficient remuneration for Labor performed or alternatively inadequate interest on Capital invested.

## SOME POPULAR FARMING FALLACIES.

[Address delivered by MR. W. J. SPAFFORD (*Deputy Director of Agriculture*) at the Forty-first Congress of the Agricultural Bureau.]

The belief in remarkable happenings which have little other than traditional support appears to be a common characteristic of human beings. There is that customary tendency to blindly believe some things without attempting to arrive at the truth, no matter how extraordinary the supposed influence or alleged happening might be, and it is only when a doubt is forcibly brought under notice that any attempt is made to investigate the matter. This certainly applies to a number of subjects connected with agricultural practices, and as some of these beliefs tend to hamper progress, a few of the more important are presented in this paper, to focus attention on them and to lead to some doubt as to their validity.

It is felt that despite the advance that has taken place in scientific knowledge in recent years, it is remarkable how strong is the belief in some of these alleged phenomena, and the sooner a clear understanding of these unusual occurrences is gained, the sooner will improvements and advancement be made in their direction.

The subjects being discussed are:—

*Blighting of Wheat Crops by Superphosphate.*

*Telegony.*

*Intra-uterine Influences.*

*Change of Seed.*

*Oats better than Barley as a Livestock Foodstuff.*

*Weevil develop spontaneously.*

*Stage at which Oats should be cut for hay.*

### “BLIGHTING” OF WHEAT CROPS BY SUPERPHOSPHATE.

Ever since Superphosphate was introduced into South Australian farming practices as a fertiliser for wheat crops, the idea that wheat will be “*blighted*” by the liberal use of this manure has persisted. In all of the Wheat-growing districts of the State there was a time, and that not long ago, when the maximum quantity of Superphosphate considered safe to use was very low. With the advancement of time, however, the average dressing of Superphosphate per acre has gradually increased throughout our wheat-growing areas, and as a consequence the alleged dangerous maximum application has also increased. Still, despite the fact that farmers have so often changed their opinions as to the exact amount of this fertiliser which will injure crops, many of them persist in the belief that the safety limit is only just a little ahead of the average dressing of the district in which they are farming. That these notions have had to be adjusted fairly rapidly will be realised by those who remember that as recently as 1915 there was a fair sprinkling of farmers in some of our Lower North districts who believed that it was unsafe to apply more than 60 to 70lbs. of Superphosphate (36 per cent.) to the acre, with wheat sown on fallowed land. In some of those districts at the present time the average dressing of Superphosphate applied to all annual crops grown, including Oats, Barley, and Peas, is over 100lbs. per acre, and most of this manure is what is known as 45 per cent. grade. In this connection all annual crops sown in the whole of County Light received an average of 117lbs. Superphosphate per acre, in

County Gawler the dressing is 112lbs., and in County Fergusson 109lbs. per acre, and these relatively high average dressings mean that some farmers are using around about 2cwts. of Superphosphate per acre with their wheat crops.

The term "*blighting*" is generally applied to that trouble with wheat crops when the moisture is dried out of the plants quicker than the roots can make it good, and is usually characterised by the plants going straight from the green to the dry stage without showing the natural changes of color which accompany normal ripening. In a mild attack the grain is badly pinched; in bad cases the plants dry out in a few days to a whitish color and become very light in weight; and there may be all stages in between these two extremes.

Even a mild attack of "*blighting*" always means a considerably decreased yield, and a much reduced weight per bushel of the grain that is harvested, and to show that neither of these happenings occur in South Australia from the use of Superphosphate, the following results of field experimental work with various dressings of Superphosphate are submitted:—

*Yields of Wheat grown with Various Dressings of Superphosphate.*

| Location of Experiments.  | Average Annual Rainfall. | Duration of Experiment. Years. | Mean Yield per Acre. Superphosphate per Acre. |      |       |      |       |      |
|---------------------------|--------------------------|--------------------------------|-----------------------------------------------|------|-------|------|-------|------|
|                           |                          |                                | No Manure.                                    |      | ½cwt. |      | 1cwt. |      |
|                           |                          |                                | Bush.                                         | lbs. | Bush. | lbs. | Bush. | lbs. |

| Means (108 Crops) .....   | —                        | —                              | 11                                            | 28   | 15    | 26   | 16    | 53   |

These experiments, which were conducted in nineteen wheat-growing districts of the State with an average annual rainfall varying from just over 10½in. to about 19in., show a consistent increase in the wheat yield as heavier dressings of Superphosphate are applied, and it appears that no matter what the climatic conditions obtaining, comparatively heavy dressings of Superphosphate do not "*blight*" Wheat crops, at all events to the extent of reducing the yield of the crops so treated.

The next Table sets out the weight per bushel of Wheat produced at Roseworthy Agricultural College, when grown with different dressings of Superphosphate, for each of the past twenty-five years.

TABLE II.—*Weight per Bushel of Wheat Grown with Various Dressings of Superphosphate.*

| Year.                  | Superphosphate per Acre. |                    |                  |                  |
|------------------------|--------------------------|--------------------|------------------|------------------|
|                        | No Manure.               | $\frac{1}{2}$ cwt. | 1cwt.            | 2cwt.            |
|                        | Lbs.                     | Lbs.               | Lbs.             | Lbs.             |
| 1905                   | 63 $\frac{1}{2}$         | 63                 | 62 $\frac{1}{2}$ | 63 $\frac{1}{2}$ |
| 1906                   | 59                       | 58 $\frac{1}{2}$   | 58 $\frac{1}{2}$ | 57 $\frac{1}{2}$ |
| 1907                   | 63                       | 63 $\frac{1}{2}$   | 62 $\frac{1}{2}$ | 63 $\frac{1}{2}$ |
| 1908                   | 64 $\frac{1}{2}$         | 63 $\frac{1}{2}$   | 64 $\frac{1}{2}$ | 64 $\frac{1}{2}$ |
| 1909                   | 62 $\frac{1}{2}$         | 63                 | 62 $\frac{1}{2}$ | 63               |
| 1910                   | 64 $\frac{1}{2}$         | 64 $\frac{1}{2}$   | 64 $\frac{1}{2}$ | 63 $\frac{1}{2}$ |
| 1911                   | 64                       | —                  | 63 $\frac{1}{2}$ | 63 $\frac{1}{2}$ |

\*23 years only.

The mean weight per bushel of the wheat produced with different manurial treatments as seen above certainly favors that from the plots not manured, but the difference between it and the plots regularly manured is not sufficiently great to ascribe it to the "blighting" of the crops receiving Superphosphate. As a matter of fact, nearly the whole difference is to be seen in the weight of the wheats of 1913 and 1915, when the "No Manure" plot had a considerable advantage, in that Red Rust was very bad on the manured plots in 1913, and in 1915 the fertilised plots made rank growth in the very favorable growing season, and then suffered to a slight extent in the dry Summer of that year, because of their early luxuriance.

On the experience gained in wheat-growing in South Australia, it appears that "blighting" of wheat is never directly due to application of Superphosphate, no matter how heavy the dressings, and it seems that the erroneous idea has risen from the fact that much of our wheat land, when originally opened up for cropping, was excessively rich in organic matter, which substance will lead to the "blighting" of the cereals. The extreme case in this connection is of common occurrence, for where hay has been stacked it is usual for the first three or four cereal crops grown on the site, after the land has again been brought under crops, to "blight" very badly. The same thing applies to old sheep camps, and in all places where there is an excess of organic matter in the soil.

Perseverance in the idea that heavy dressings of Superphosphate tend to reduce yields of wheat crops by "blighting" the plants, is delaying our agricultural progress, and the sooner it is realised, that in South Australia at all events, there is no danger whatever of such a happening, the more rapid will be the advance towards the utilisation of the most profitable applications of Superphosphate for our wheat crops.

## TELEGONY.

The term *Telegony* has reference to the traditional belief in the theory that a sire used on a dam leaves some influence in that dam which may affect future offspring by other sires. This opinion is so firmly held by some breeders, that they maintain that a female once mated to a sire of a different breed is no longer of use for the breeding of pure-breds. The influence on offspring of a previous impregnation is more particularly considered as applying to horses, dogs and man, but breeders of other kinds of livestock have such trust in the assumption, that it has led, in different parts of the World, to the adoption of special rules to exclude from registration in various herd books females which have been mated to a sire of a different breed.

It is rather remarkable that such a tenaciously held traditional belief should have been developed from a few isolated instances, but it certainly seems to be so, and as a matter of fact, it appears, in English-speaking countries at all events, that much of the strength of the belief is based on the single case of Lord Morton's mare. Lord Morton had a virgin chestnut Arab mare—seven-eighths pure—mated to a male Quagga. The resulting female hybrid, plainly showed in shape and coloring that it was a hybrid. Sir Gore Ouseley, who purchased the mare, mated her with a black Arab stallion two years in succession; the first year a filly resulted, and the next year a colt was foaled. The following description of this filly and colt by the Arab stallion is given in a letter from Lord Morton to the President of the Royal Society, as quoted by Babcock and Clausen (i.) :—

"The two-year-old filly and yearling colt have the character of the Arabian breed as decidedly as can be expected where fifteen-sixteenths of the blood are Arabian; they are fine specimens of that breed, but both in the color and in the hair of their manes they have a striking resemblance to the Quagga. Their color is very marked, more or less like the Quagga in a darker tint. Both are distinguished by the dark line along the ridge of the back, the dark stripes across the forehead, and the dark bars across the back part of the legs. The dark stripes across the forehead of the colt are confined to the withers and to the part of the neck next to them. Those on the filly cover nearly the whole of the neck, and the back as far as the flanks. The color of her coat on the neck adjoining to the mane is pale and approaching to dun, rendering the stripes more conspicuous than those on the colt. The same pale tint appears in a less degree on the rump, and in this circumstance of the dun tint also she resembles the Quagga.

"Both their manes are black; that of the filly is short, stiff, and stands upright, and Sir Gore Ouseley's stud groom alleged that it never was otherwise. That of the colt is long, but so stiff as to arch upward and to hang clear of the sides of the neck, in which circumstance it resembles that of the hybrid. This is the more remarkable, as the manes of the Arabian breed hang lank, and closer to the neck than those of most others. The bars across the legs, both of the hybrid and of the colt and filly, are more strongly defined and darker than those on the legs of the Quagga, which are very slightly marked; and though the hybrid has several Quagga marks, which the colt and filly have not, yet the most striking—namely, the stripes on the forehead, are fewer and less apparent than those on the colt and filly."

Dealing with this case of the progeny of Lord Morton's mare, Professor E. Davenport (ii.) makes the following pertinent remarks:—

"It is one of the best evidences of the power of tradition that this single instance, happening more than a hundred years ago, has done duty ever since to prove (†) an exceedingly doubtful theory and an almost unaccountable belief. It is remarkable that so uncertain a circumstance, and one so easy of repetition, with universal experience tending constantly to throw light upon the subject, should have been so excessively over-worked. It shows, as no other instance has ever shown, the persistence of tradition, the extent of credulity in the presence of the phenomenal, and the willingness of men to repeat an assertion, or even an opinion, until by mere repetition it comes to have all the

force of authority. Without a reasonable doubt belief in *telegonic influence* rests upon stray instances, difficult of understanding by those who happened to be the observers, and hastily accepted as evidence. A single instance may be good negative testimony, but it is seldom worth much as positive evidence. . . . The thanks of the World are due to Professor Ewart for his excellent work in disposing, by direct experiment, of a citation that has done damage long enough."

Professor Cossar Ewart (iii.), of Edinburgh, carried out extensive breeding experiments with animals to determine whether such a doctrine as *telegony* is tenable, but in every case he was forced to the conclusion that alleged cases of infection may be accounted for most easily and most satisfactorily as instances of reversion to ancestral types. The illustrations from Ewart's work, having direct bearing on the case of Lord Morton's mare, and quoted by Babcock and Clausen (i.) are as follows:—

Professor Ewart mated the Burchell Zebra stallion "Matopa" to a chestnut Polo-pony "Valda," and twin hybrids resulted. The next year she produced a foal to a light-chestnut Thoroughbred stallion, after which she produced a third hybrid foal by "Matopa." Subsequently she produced another foal to a dark chestnut Thoroughbred stallion. The three hybrid foals from this mating were all richly striped, the stripes being more numerous, although less conspicuous, than those of the Zebra sire. The two foals produced from "Valda" by Thoroughbred sires, in no particular, either in color or form, resembled the hybrid foals, being chestnut in color without any suggestion of striping.

In a further experiment, Professor Ewart mated the Zebra stallion "Matopa" to a black West Highland pony "Mulatto," the result being a distinctly striped hybrid colt. The mare "Mulatto" was then mated to a black Arab stallion, and produced a foal which, when examined immediately after birth, showed numerous indistinct markings, so faint however, that their exact nature was in some doubt. Subsequently, "Mulatto" produced another foal by a dark-brown West Highland stallion which was also indistinctly marked. These foals suggested that, as in the case of Lord Morton's mare, *telegony* might occasionally occur. Professor Ewart, however, tested the matter further by mating two mares closely related to "Mulatto," to the same black Arab stallion which had sired the striped foal. Two foals were produced, one possessing indistinct markings similar to those on "Mulatto's" foals, whilst the other was more distinctly striped. There can be no question, therefore, that the striping of "Mulatto's" foals was a *consequence of normal hereditary processes* having nothing to do with *telegony*.

As Professor Ewart points out, there is abundant evidence that striping is common in horses, especially those of Oriental origin. Modern breeds of horses were largely derived from the forest type of Wild-horse of a yellowish-dun color, and this type had a dark stripe down the back, marks on the legs, and sometimes on face, neck, and withers. To-day it is not uncommon to get distinct markings on mongrel ponies, and certainly so with Arab crosses.

Babcock and Clausen (i.) give other interesting examples of direct experimental work in this direction, and amongst them they state:—"The evidence from Mule-breeding establishments where thousands of mules have been produced is all against the *doctrine of telegony*. Mumford has recorded a large number of concrete cases in support of the position. In a few instances mares have produced as high as ten, or eleven mule foals before they were bred to stallions, yet in not a single case was there positive evidence of *telegony*."

An instance (i.) dealing with dogs which Professor Ewart quotes is of considerable interest in this connection. A tan Dachshund bitch was mated to a tan dog, and produced a litter of pups having white bodies and tan cheeks and ears. This bitch had previously borne a litter of pups to a white Fox-terrier with tan cheeks and ears. Presumably both the tan Dachshund bitch and dog had long lines of tan or black-and-tan ancestors, so it was natural to conclude that this was a sure case of *telegony*. But

the breeder to whom the attention of this instance was called remarked that although the color of the pups was strongly reminiscent of the white Fox-terrier, the form and general characteristics were otherwise those of pure Dachshunds. Accordingly, he traced the pedigree of the dam and found that in the sixth generation it ran back to the kennel of a lady whose hobby was white Dachshunds with tan cheeks and ears. This particular mating had simply given opportunity for the expression of latent characters carried by the tan dogs. It was a perfectly intelligible case of *reversion*, not *telegony* at all.

Plenty of other examples could be quoted to show that where it has been alleged that instances of *telegony* have occurred, further investigations into the ancestry of the individuals concerned or direct experimental work, clearly demonstrate them to be cases of *reversion*. Even if there was some possibility of this weird notion, as conveyed in the term *Telegony*, occasionally proving true, it will be of such rare occurrence, judged by the very few cases on which the theory has been developed, that breeders need not anticipate trouble in this direction. As a matter of fact, until some positive evidence has been brought forward in support, it can be taken as a non-existent law of breeding.

#### INTRA-UTERINE INFLUENCES.

In all probability there are few things affecting breeding more widely believed in than the alleged effect of external happenings on the young still being carried in the uterus of its mother. It is common belief that imagination, strong mental impressions, emotions, frights, etc., of a pregnant female, are likely to lead to structural changes in the unborn offspring, and such alleged experiences have been used as the explanation for malformations, birth-marks, peculiarities, and for abnormalities of any and every kind that occur with human beings and other animals. The confidence of most people in *Maternal Impressions* or *Pre-natal Influences* is so well established that it often affects breeding practices, and it is still not unusual for some breeders to have certain colors exhibited before females while they are being served, when it is desired to secure young animals of that particular color, whilst others blindfold the female during service, and only remove the bandage after an animal of the desired color has been placed before her, so that the first thing seen after impregnation will be of the color wished for. These practices are only modifications of Jacob's methods of securing certain markings on animals, as carried out some thousands of years ago, and recorded in the Scriptures in the 30th chapter of Genesis. You will remember that Jacob went to work for his uncle, Laban, and contracted to labor for seven years to have Rachel given him as wife, and at the completion of the term had the elder daughter Leah foisted upon him instead, but, after a further seven years' work, he took Rachel as wife as payment for this period of labor. He continued as herdsman for Laban, stipulating that after a given date he should take all the speckled and spotted goats, cattle, and sheep which were born in Laban's flocks and herds, as wages for his hire. On the appointed day, all the speckled and spotted animals were removed from Laban's herds, and to ensure full payment for his labors, Jacob practised the methods described in verses 37 to 43 of Genesis xxx.:—

37. And Jacob took him rods of green poplar, and of the hazel and chestnut tree; and pilled white strakes in them, and made the white appear which was in the rods.

38. And he set the rods which he had pilled before the flocks in the gutters in the watering troughs when the flocks came to drink, that they should conceive when they came to drink.

39. And the flocks conceived before the rods, and brought forth cattle ring-straked, speckled and spotted.

40. And Jacob did separate the lambs, and set the faces of the flocks toward the ring-straked, and all the brown in the flock of Laban; and he put his own flocks by themselves, and put them not unto Laban's cattle.

41. And it came to pass, whensoever the stronger cattle did conceive, that Jacob laid the rods before the eyes of the cattle in the gutters, that they might conceive among the rods.

42. But when the cattle were feeble, he put them not in; so the feeble were Laban's and the stronger Jacob's.

43. And the man increased exceedingly, and had much cattle, and maidservants, and menservants and camels and asses.

This classic case from the Old Testament, so often quoted in support of the power of Maternal Impressions, is the sort of explanation expected from the less-skilled towards the success of a highly-skilled breeder such as Jacob, who obviously knew how to mate animals together with a big chance of securing spots and speckles.

Such theories as *Intra-uterine Influences*, *Telegony*, etc., appear to have developed because of the impression made on the mind by rare and uncommon occurrences, and the ordinary happenings of life are ignored when considering these sensational events. As a matter of fact, in view of recent investigational work, this doctrine of *Maternal Impressions* appears to be particularly unreasonable, because it now seems certain that other than the natural characteristics the offspring will inherit from its mother, the fetus is only dependent on its mother for nourishment. This fact is brought out by experiments made by Mr. Walter Heape, of Cambridge (ii.), dealing with the transplantation of ovaries from one female to another:—

“Two segmenting ova were obtained from an Angora doe rabbit, which had been fertilised by an Angora buck 32 hours previously and were immediately transferred to the upper end of the fallopian tube of a Belgian Hare-rabbit which had been fertilised three hours before by a buck of the same breed as herself. In due course this Belgian Hare-doe gave birth to six young. Four of these resembled Belgian Hare-rabbits, but the other two were undoubted Angoras. Both of the Angoras were born bigger and stronger than any of the other young, and they all along maintained their supremacy in this direction.”

In view of the fact that when the undoubted breeding of animals is known for a sufficient number of generations, it can be foretold with certainty what the offspring will be like when two of the same breed are mated together, and also when we remember that various breeds of the different kinds of animals have been kept true to type so long, it does seem wonderful that people can believe a theory which makes such extravagant claims as does this *Intra-uterine Influences*. The statement made by Darwin (iv.), when writing to Sir Joseph Hooker on the subject, gives the true explanation of many of the alleged cases. He said:—“W. Hunter told my father, then in a lying-in hospital, that in many thousand cases he had asked the mother before confinement whether anything had affected her imagination and recorded the answers, and absolutely not one case came right, though when the child had anything remarkable they always made the cap to fit.”

If all these small things, such as seeing certain colors, mental agitations, worries, accidents, frights, etc., were liable to affect the young being carried by their mothers, what a confused mixture of colors all our animals, including man, would consist of in these days of gaudy advertisements and bright colorings generally; what a collection of maimed youngsters would be about because of the frights from motor cars and other fast travelling vehicles; and it appears almost impossible to visualise the enormous numbers of malformed children that would have been born from 1915 to 1919 in those countries where the Great War was fought.

There are no proved cases of young animals being marked or changed from the normal by external influences whilst still in the uterus; alleged happenings in this

direction have never been reproduced under controlled conditions; and fortunately even the alleged happenings are of such rare occurrence that breeders need fear no interference from this source.

#### CHANGE OF SEED.

Throughout the grain-growing districts of the country, and it appears to be World-wide, there is a strongly held belief in the necessity for changing seed. It is contended that the continuous growing of a variety from seed produced on the one farm naturally leads to a rapid deterioration of that seed, and if the variety is to be persisted with, it then becomes necessary to secure seed from a different source. The reliance placed by some growers on change of seed as a means of increasing yields of crops is so highly regarded that they always purchase seed to be used from outside sources, and would never think of using seed grown on their own farms for a number of years, or for that matter will not even use seed grown in their own district. This belief is the more remarkable, because in all cases where carefully conducted investigations, on the matter have been carried out, and *where ordinary reasonable care has been taken to prevent deterioration of the seed produced*, home-grown seed gives better results than does seed of the same kind produced in another locality.

A considerable amount of work has been done in testing this question of the effect of change of seed in many grain-growing countries, but perhaps of that done under field conditions, there is nothing more thorough and important than that undertaken by Professor G. W. Shaw, of the University of California. Professor Shaw, who has four Agricultural Experimental Stations under his control, grew wheat at these stations, and sent seed to different parts of the State, where it was grown for varying periods before being returned to its original home. On the return of the seed from private farms, it was grown alongside seed which had been continuously grown on the Station farm, and without a single exception the "home" seed gave greater returns than the "change" seed. In reporting on the results of the investigations Professor Shaw stated—"Loss always occurs by mere change of seed, except only when there is a better type of wheat or more vigorous grain of the same type."

In our own State, "Gluyas" and "King's Early" have been grown continuously at Roseworthy Agricultural College for thirty-five years and both varieties are a good deal better now than they have been at any time in that period.

If seed is deteriorating to the extent of requiring replacement by seed from another locality, it shows that ordinary care has not been taken with it, and the *deterioration is the result of neglect*, and is not due to continuously growing it on the one farm.

#### OATS BETTER THAN BARLEY AS A LIVESTOCK FOODSTUFF.

With quite a number of livestock breeders and farmers generally, at all events with those of European origin, there is a firmly fixed fancy that Oats are a much better foodstuff for livestock than is Barley. Some of these people go as far as to claim that Barley is not even a useful feed for the large farm stock; others feel that when using Barley the point above which it becomes dangerous to increase the amount given to the animals is quickly reached, except for pigs; whilst others again, although using Barley for all kinds of animals, consider that it is only a fattening foodstuff and quite unsuitable for any other purpose. It appears that this notion is a European prejudice developed through lack of knowledge of feeding with Barley, because it is quite common to hear the expression, "*You cannot use much Barley for farm livestock because it is too heating*," whereas in Mediterranean countries, where much Barley is grown and Oats are not well known, and where the climate is at least as hot as is our own, the idea of the feeding value of these two grains is expressed in, "*You cannot use much Oats for farm livestock because they are too heating*." That these ideas of the value of the two grains must be a matter of lack of experience is easily seen by a look at the figures presented in Table III., which are based on the results of actual feeding experiments.

\*\*\* (v.) European samples quoted by O. Kellner.

(vi.) Roseworthy Agricultural College, by A. T. Jefferis and C. S. Piper.

(vii.) Roseworthy Agricultural College, by Professor A. J. Perkins.

When foodstuffs of the same type are to be compared, the *Starch Equivalent method* as advocated by Professor O. Kellner appears to give a very close approximation as to how they will be utilised when fed to livestock, and when they are to be used for maintenance or fattening purposes, this method of estimating their value can be used with a good deal of confidence. If to be used for the production of milk, as for milking cows, ewes with lambs, etc., or for work, as with horses, this method of comparison may need some modification, because the amount of digestible protein present in the foodstuff and its relationship to the other digestible nutrients, affect its value for these purposes. In any case, a glance at the figures in the above table shows that not only is the Starch Equivalent value of the Barleys much above that of the Oats, but that with the single exception of the flat grains of European Oats, with the high content of 10.2 per cent. digestible protein, the good Barley samples contain nearly as much digestible protein as do the various Oat samples. These figures show very clearly that *for maintenance and fattening purposes Barley is worth more, pound for pound, than are Oats, and that for the production of milk and work a good sample of Barley is at least equal to Oats.*

Barley is gradually being recognised as a suitable foodstuff for Sheep as well as for pigs, and a few farmers have begun using barley for Dairy Cows, particularly in those places where Lucerne is one of the principal foods supplied to the Cows, but we have yet to reach the stage when Barley will be looked upon as the chief concentrated foodstuff supplied to all farm livestock, including milking cows and working horses. It is of the utmost importance that we give this question of the feeding of home-grown Barley to our farm livestock the most serious consideration, because we can grow Barley very readily in so much of our Wheat-growing country, whereas only some of it grows heavy crops of good quality Oats.

#### WEEVILS DEVELOP SPONTANEOUSLY.

Despite the fact that much information was broadcasted throughout the State at the time when *weevils* were doing so much damage to the wheat stacked for the British Government during the Great War, and also that so many farmers have known *weevils*

to be present in their barns for a great number of years, there are still a lot of people who have to handle cereals who firmly believe that *weevils* develop from inside the grain, and that grain only has to be enclosed in a receptacle of some kind, and *weevils* will spontaneously appear. Some explain this alleged happening by making the assertion that the weevil "germ"—whatever that might be—finds its way into the grain at flowering time or soon after. Of course there is no such happening as spontaneous generation, at all events not where a relatively high form of life like a *weevil* is concerned, and the persistence in such a belief only delays the day when methods of control will be understood and practised.

The life history of the *weevils* which do so much harm to stored grain is thoroughly well-understood for all sets of natural conditions where they are troublesome, and for the principal *weevil* found in this country, viz., the Rice Weevil (*Calandra oryzae*), it is somewhat as follows:—

A female *weevil* which has been fertilised by a male makes a groove or a hole in the skin of a cereal grain, without being particular as to the situation of the hole, and lays an egg in the opening. From this egg a small yellowish-white grub with a brownish head and without legs, hatches out, and as it is then in close contact with its food supply it immediately begins eating the inside of the grain. In warm weather the grub remains as such for about 14 to 18 days, when it turns to a chrysalis. It remains for 3 to 9 days in this form, after which it emerges as a perfect insect and continues to feed on the inside of the grain, and eventually it eats its way out and goes in search of a mate. In the beetle stage the *weevil* does more damage than when in the grub stage.

A considerable amount of work has been done in connection with *weevils* in most grain-growing countries of the World, and as a consequence it is known that in a climate such as our own, in the warm part of the year, it takes about 19 to 22 days for *weevils* to develop, between the egg and the perfect insect, and that four generations can be expected each year, whereas in tropical countries six broods a year can be anticipated. As each female lays about 150 eggs it is easy to realise what are the theoretical possibilities of producing *weevils* if all eggs hatched and all grubs developed during six generations, but as this theoretical maximum is never even approached in nature, it is only interesting to contemplate the countless millions that might result. Under actual counts it is found that during a normal summer one pair of *weevils* will produce a total of about 6,000 insects.

There is no mystery about the development of the *weevil*, and it is perfectly well known that before grain can become infested by *weevils* it must come in contact with mature female insects, so that they can lay their eggs inside the skin of the grains. A realisation of this fact is necessary before proper control methods can be taken to combat the pest.

#### STAGE AT WHICH OATS SHOULD BE CUT FOR HAY.

The practice has developed in this State of allowing Oat crops to become almost ripe before cutting them for hay. Very few farmers commence cutting Oat crops until much of their green color has gone and until they show a lot of purplish coloration in the stalks, and so by the time the cutting is completed a good deal of the crop is nearly ripe. This practice has led to the development of an accompanying habit of judging the quality of Oaten Hay-chaff by taking a double handful of the chaff, blowing the chaffed stalks away from the grain, and carefully examining the grain left in the hands. If there is a lot of well-developed grain in the chaff it is considered by many to be really good Oaten Hay-chaff.

This practice seems to have developed because of two reasons:—(a) In those parts of the State where power threshers are in use, the method of handling much of the Oat crop has been to allow it to approach maturity, cut it with a binder, and store it in stacks; if the price for Oats is good that season the stack is threshed and the grain

sold, but if more money is to be made from hay, the stack is chaffed and sold as Oaten Hay-chaff. (b) In most of the State the principal variety of Oat grown is the one known as "Algerian," and an unwarranted prejudice has developed which has led to the belief that this particular variety of Oat is *bitter* during all stages of its growth up to the time it approaches maturity, and it is considered that this *bitterness* is not overcome until the plants show a good deal of purplish color in the stalks.

It is gradually being realised as time goes on that this *alleged bitterness* of green Oats is an unjustifiable assumption, and it is now becoming recognised that any gain made in palatability by waiting until the green stage is almost past, is more than compensated for by the loss of nutriment. This fact is clearly brought out in the following analysis of Oats cut at different stages of growth:—

TABLE IV.—Oats Cut at Different Stages of Growth (v).

|                         | Before Heading.  |                       | In Flower.       |                       | Ripe.            |                       |

| Protein.....            | 12.9             | 9.7                   | 7.4              | 5.3                   | 6.6              | 4.5                   |
| Fat .....               | 2.8              | 2.0                   | 2.3              | 1.6                   | 2.3              | 1.5                   |
| Carbohydrates .....     | 44.7             | 28.2                  | 40.3             | 25.4                  | 39.6             | 24.2                  |
| Fibre .....             | 21.2             | 12.7                  | 33.0             | 18.2                  | 36.1             | 15.9                  |
| Starch Equivalent ..... | 41.5             |                       | 32.5             |                       | 26.2             |                       |

These figures, and particularly those representing the Starch Equivalents, show how rapidly the Oat plant loses its nutriment as it approaches maturity, and how delaying the cutting-time until near ripeness reduces the value of the hay eventually secured. These Starch Equivalent values mean that 1 ton of hay made from Oats in flower are equal in feeding value to 24.8cwts. of ripe Oats. It is recognised, of course, that hay made from Oats cut at flowering would have a slight tendency to scour working horses, or would be, as we say, too "*soft*" a feed for workers, but the longer the delay after flowering before cutting oats for hay, the poorer the feed-value of the hay cured. In making oaten hay for cows in milk, the crop should be cut at or near flowering time, whereas if required for working horses it should be cut ten days to a fortnight after flowering, and while the grain is still in the "*milky*" stage.

## SUMMARY.

### *Blighting of Wheat Crops by Superphosphate.*

1. The trouble known as "*blighting*" of wheat crops is characterised by the plants going straight from the green to the dry stage without showing the natural changes of color which accompany normal ripening.

2. In a mild attack of "*blighting*" the grain is badly pinched and the yield considerably reduced.

3. As the recorded yields from 19 centres in the State, with up to 17 consecutive years' crops, show a consistent increase in yield as the amount of Superphosphate is increased up to 2cwts. per acre, and as the weights-per-bushel for the past 25 years from the Wheat plots receiving various dressings of Superphosphate at Roseworthy Agricultural College do not show much variation, it seems certain that in South Australia there is no danger of "*blighting*" being caused by relatively heavy applications of Superphosphate.

### *Telegony.*

4. The term *Telegony* refers to the traditional belief in the theory that a sire used on a dam leaves some influence in that dam which may affect future offspring by other sires.

5. This traditional belief has been developed from a few isolated cases, and in many places the notion has been raised on the single instance of Lord Morton's mare.

6. The classic and overworked case of the crossing of Lord Morton's Arab mare with a Quagga, and then securing striped foals from her when mated to Arab stallions, has been disposed of by the experiments of Professor Cossar Ewart, of Edinburgh.

7. In all alleged cases of *telegony*, further investigation into the ancestry of the individuals concerned, or direct experimental work, have clearly demonstrated them to be cases of reversion.

8. The alleged cases have been rare, and all have been disposed of where investigated, and so until some positive evidence is forthcoming it can be taken that *telegony* is a non-existent law of breeding.

#### *Intra-uterine Influences.*

9. The term *Intra-uterine Influences*, also known as *Maternal Impressions* and *Pre-natal Influences*, refers to the alleged effect of external happenings on the young still carried in the uterus of the mother.

10. It is very doubtful if there is anything else connected with breeding so firmly established and so widespread, as faith in this traditional belief.

11. Even at the present day, modifications of Jacob's methods of thousands of years ago, to secure certain results by affecting the fetus, are being practised by some breeders.

12. Following on the experiments of Heape, it appears certain that other than the natural characteristics the offspring will inherit from its mother, the fetus is only dependent on its mother for nourishment.

13. When a child is born with any peculiarity, the mother, guided by tradition, hunts for some experience in the preceding months, and usually succeeds in finding one to fit the occasion.

14. Alleged cases of young animals being marked or changed from the normal whilst still in the uterus have never been reproduced under controlled conditions, and in any case the alleged happenings are of such rare occurrences that breeders need fear no interference from this source.

#### *Change of Seed.*

15. It is often contended that continuously growing seed on the one farm leads to deterioration, and that it is frequently necessary to change the seed.

16. Considerable work has been done in this connection with the grain crops; and Professor G. W. Shaw of California sums up the position well, when he says:—"*Loss always occurs by mere change of seed, except only when there is a change to a better type of wheat or more vigorous grain of the same type.*"

17. If seed is deteriorating to the extent of requiring replacement, it shows that ordinary care has not been taken with it.

#### *Oats Better than Barley as a Livestock Foodstuff.*

18. Oats are favored as a foodstuff in this country as against Barley, because it is considered that in this climate Barley is too heating for livestock, whereas in other hot countries where Oats are not well known they are objected to because they are more heating for livestock than is Barley.

19. Analyses show that for fattening and maintenance purposes, Barley is worth more pound for pound than is Oats, and that for the production of milk and work, it is about equal to Oats.

20. It would prove advantageous to the State to adopt Barley as the principal grain-feed for all farm livestock, because we can grow the crop well in most of our wheat-growing districts.

#### *Weevils Develop Spontaneously.*

21. There is no such thing as spontaneous generation for relatively highly developed insects like weevils.

22. The *female weevil* lays eggs in holes she has made in the skin of grains which hatch as small yellowish-white grubs. The grub lives on the inside of the grain about a fortnight or more, then changes to a chrysalis, in which form it remains for 3 to 9 days, after which it emerges as a perfect insect. The insect eats out the inside of the grains and eventually comes out and goes in search of a mate. In our climate, four generations of *weevils* can be expected each year.

*Stage at which Oats should be Cut for Hay.*

23. Oats are generally allowed to approach maturity before they are cut for hay.

24. Analyses and feeding results show that the Oat plant rapidly loses its nutriment as it approaches maturity.

25. Oaten hay for cows should be cut as near flowering time as possible, and if to be used for working horses the cutting should be done about 10 to 14 days after flowering.

## IMPROVEMENT IN FARM POULTRY.

---

[Paper read by MR. C. F. ANDERSON (*Acting Poultry Expert*) at the Forty-first Congress of the Agricultural Bureau.]

---

It is generally realised that in common with all other lines of primary produce, costs in poultry egg production must be reduced, and there is undoubtedly room for improvement, especially in farm poultry.

For some years egg production in South Australia has been limited to farm poultry, but during the last eight to ten years conditions have been undergoing a change. Following on the work which has been done and which is still going on at the Parafield Poultry Station, which has been the medium of establishing commercial poultry farming in South Australia, large numbers of poultry producers concentrating all their efforts on poultry breeding have established modern poultry farms in various parts of the State, until to-day commercial poultry farming is a soundly established industry in South Australia, and is rapidly expanding. Mammoth incubators have been installed, large brooder houses built, modern scratching sheds to hold hundreds of birds erected, and proper attention paid to breeding, feeding, and the marketing of eggs. As a result, at least 30 per cent. of the eggs marketed in Adelaide to-day are produced by commercial poultry men, and the production of this class of egg is rapidly increasing. The question may be asked, "What effect this has on farm poultry?" It has meant that with the increasing quantities of high quality eggs it is becoming more difficult each year to dispose of the lower quality eggs.

It must be borne in mind that the difference in quality between the farm egg and a commercially produced egg, especially in the early part of the season, when ample supplies of succulent green feed are available, is not very noticeable; but as the summer approaches, green feed becomes rank and tough on the average farm, whereas the commercial poultry farmer feeds large quantities of green feed grown under irrigation, and so the commercially produced egg is of much better quality.

It is especially desirable at the present juncture that every effort be used to increase exports; in fact, it is essential to the stability of the poultry industry that this be accomplished. It is very doubtful, however, if 20 per cent. of farm produced eggs are suitable for export. Commonwealth export regulations demand:—

- (a) All eggs shall be individually examined by the candling process.
- (b) Eggs which have been subjected to any preservative process or which have been placed in cold store prior to being submitted for export shall not be packed.
- (c) Any egg which has a broken or damaged shell, or which is in an unsound or other abnormal condition, shall not be packed.
- (d) All eggs must be perfectly clean, *i.e.*, they must be free from stain, dirt, and other foreign matter.
- (e) All eggs must be fresh, *i.e.*, after examination by the candling process are, in the opinion of an officer, fit for human consumption and are not more than seven days old.

These regulations may, to the inexperienced, appear rather drastic, but after careful analysis they only mean that the eggs must be new laid, perfectly clean in the shell, and free from abnormalities. With a little care in regard to clean nest accommodation, getting the eggs to the packing floor as quickly as possible after being laid, the exportable quantities would be largely increased.

For instance, if during the months of export—August, September, and October—there are 200,000 dozen eggs per week coming on to the Adelaide floors from the farms, 20 per cent. of these is equivalent to 40,000 dozen suitable for export, leaving a balance of 160,000 dozen eggs per week which are thrown back on the local market, because they

are not up to export standard. This will convey some idea of the serious effect these eggs have on the market for the remainder of the year, besides the actual financial loss suffered, through not being able to ship these eggs.

**METHODS WHERE IMPROVEMENT CAN BE EFFECTED.**

1. *The Keeping of a Better Class of Stock.*—Pure breeds are infinitely better producers than crossbreds. South Australian White Leghorns are world renowned as egg producers; Black Minorcas are also good layers of large eggs. Black Orpingtons, Rhode Island Reds, and Barnevelders are specially suited for farm conditions. When purchasing stock, obtain same from only birds laying full-sized 2oz. eggs and over. Remember that the size of the egg is more a matter of strain than of breed. Several strains of Leghorns are noted layers of large eggs, whilst others are only able to produce small eggs.

2. *Hatching Methods.*—For years the average farmer has depended too much on the hen as a means of hatching, with the result that his hatching has not been started until the commercial man has finished, principally for the reason that the average hen does not "go broody" until the warmer weather is experienced, and that is from October onwards. Hatching at this time is not profitable; late hatched birds never do well—they are slow to mature; in fact, they very seldom develop into good birds, and their egg production does not commence until the spring, when prices are low. If poultry are to be kept profitably, they must lay a percentage of eggs during the winter, when prices are highest. Late hatched birds will not do this. For winter egg production the hatching must be done during July, August, and September, according to the district and the breed of bird hatched, and the only way the hatching can be done during these months is by the incubator.

3. *The Age of the birds* is also another important factor in the profitable production of eggs. After two years of production the fowl has passed her most profitable period as an egg producer, although the best of the birds could be kept for a further 12 months as breeders.

Summarized, the following practices, if followed, would lead to general improvement in farm poultry:—

1. The keeping of pure birds only.
2. The replacement of a percentage of stock each year.
3. Hatching only during the months of July, August, and September.
4. The disposal of all birds with the exception of the very best after two years of production.
5. The disposal of all surplus male birds, to assist in the reduction of cost of feed and in the production of a higher class egg.
6. The regular marketing of all eggs—once a week during the winter and twice a week in the summer.
7. Provision of clean nests, so that eggs are marketed free from dirt and stains, &c.

## DIETS IN THE HOME.

[Paper read by MISS E. CAMPBELL (*Dip. Dom. Econ., Inspector of Domestic Arts, Education Department*) at the Women's Session of the Forty-first Congress of the Agricultural Bureau.]

Right from the time when Nebuchadnezzar, King of Babylon, besieged Jerusalem in 607 B.C., and ordered several selected young men to be fed for three years on the same meat and wine as he was using in order to prepare them as his courtiers, thought has been given to the problem of which food is necessary and best to produce good, healthy bodies. This was brought about by one of the selected youths declining the meat and wine and preferring pulse foods and water. This was his usual diet. The prince who had charge of the dietary programme was very loath to permit the change over, but after trying the simpler fare for a short period, the youths were carefully examined, and it was found that this particular young man had a better appearance, therefore he was allowed to continue with his simple diet. Much has been learnt as to the value and work of our foodstuffs since the reign of Nebuchadnezzar, and it has become a fairly common study as the means of cooking and preserving have been brought within the reach of all housewives. It falls to the mother's lot to decide each day what and how much is to be consumed by the members of her household. This is the planning of a diet or course of food to be taken by the person.

To be able to plan successfully, it is necessary to understand something of the body requirements, also to know the composition and value of the various foods that are to be made available. We all realise that the body consists of bone, muscle, sinew, nerves, blood, and water, and whether doing strenuous work or resting quietly there is work going on in the body such as breathing and the flowing of the blood. This causes a wearing away of some of the tissues; these have to be replaced by nourishing food being supplied to the body. It has been found that the body needs (1) energy for the daily work and a supply to allow for a storage of extra energy for emergency when a greater demand is made on the body. This heat to give the energy is obtained from the sugar and starch content of the food. (2) The muscles and tissues have to be repaired, and a supply has to be made available for further growth. Muscles and tissues are built up by proteins, which are the flesh-formers. (3) The blood has to be purified and the bones strengthened; this is obtained from mineral salts that we get from our foods. (4) Vitamins which are essential to growth and health; they are found in nearly all fresh foods. (5) Water is an important item, for it forms a large proportion of the tissues, and it helps to regulate the body processes. (6) Another help to regulate the body is roughage, which is obtained from vegetables.

As there are so many different duties for the food to do, and each duty can only be performed by a particular food, this gives the key to all diets—we hear of low diet, when liquids are mostly used to reduce the temperature of a patient—then there is a light diet consisting of nourishing liquids and light dishes, such as gruel, arrowroot, fish, and simple milk puddings, it is generally given to a patient in the early stages of convalescence. Another is a milk diet, supplying as much milk as the patient can be encouraged to take. There are numerous ways of serving milk—iced milk, junket, jelly, and milk drinks; this is generally given when the patient has gastric trouble. Also we hear of meat diets when it is necessary to give the body as much red juice from the meat as possible, it helps to supply blood. And we must not forget the vegetarian diet, when no meat is allowed; but the general is a mixed well-balanced diet, when every kind of foodstuff is included. Each of these diets has to be employed when necessary. The next step is to know the value of foods and how much of each to use. The flesh formers, or proteins,

are obtained from all animal foods, such as meat, eggs, milk, cheese, fish, and a small quantity from flour (wheat), peas, and beans. The heat givers, or, as they are called, the carbohydrates, are the starch and sugars; we find these in all vegetables and fruits. Fat is also a heat giver, although it is not a carbohydrate. From fruits and vegetables, a small amount from meat and milk, we procure the mineral salts to purify the blood and strengthen the bones; these are calcium, magnesium, potassium, phosphates, sodium, iron, lime, and sulphur. It was the lack of these which used to cause scurvy and other skin diseases.

Knowing what the foodstuffs will supply, it is a good housewife who can economically use the supply at hand. The work being performed by each member of the family will necessarily govern the amount demanded by the body; it is worse to be over-fed than to be under-nourished—one leads to poisons in the body, which set up most of our diseases, the other can be relieved as soon as a further supply is available, but the body in the meantime has been consuming the reserve that was stored in the tissues earlier in life. A child has to have sufficient food to supply growth and to allow for the wonderful amount of energy expended whilst playing around, he does not spare himself one atom; as he grows older the play and movements are less violent, but the muscles and bones seem to be rapidly developing. These are points that will influence the mother's decision on meals. Father must not be overlooked, for heavy work and long hours make a greater demand on the body than when the time is spent quietly with easy work. It is really the mode of life that governs the amount of nourishment to be taken, and for the body to get all its requirements it is necessary to have a mixed diet, no one particular class of foodstuff greatly predominating, but taking in all kinds of foods, such as meat, eggs, milk, fish, fruits (fresh, dried, or preserved), all kinds of vegetables (cooked and salad vegetables), cereals, bread (both brown and white), nuts, and plenty of water—either as water, tea, coffee, or other beverages—but there must be a goodly amount of liquid. This will ensure a complete supply of vitamins, proteins, mineral salts, and carbohydrates. Variety can be obtained by preparing these foods in plain or savoury dishes, but, of course, the more highly flavored the dish is the harder it is to digest, and the digestive system will rebel at any food that does not agree with it. Over cooking will destroy the value of food to the body, still the important thing is to be sure not to over eat, but give the system a fair chance to do its work, then the result will be the same as the youth before Nebuchadnezzar, he surpassed the others by ten score votes.

The women's session of the Congress concluded by a visit to the cake factory of Messrs. Ellis Bros., Franklin Street, Adelaide.

## HINTS TO SUPPLIERS.

[By W. H. DOWNES, District Dairy Instructor, South-East.]

---

### IMPORTANCE OF GOOD QUALITY CREAM.

During the last two months it has probably been noticed by cream suppliers that factories generally have been more strict in the grading of cream than was apparent during previous years. This was particularly noticeable during the export season. Although at the present time South Australia is in the position of being barely self-supporting with regard to choice butter, nevertheless there is a considerable surplus of inferior cream being delivered to the factories, which is probably accounted for to a great extent by the hotter weather being experienced and supplies of cream being smaller and held longer at the farm. In order that our local choice butter may be in the

position to successfully compete with imported butters from a quality standpoint, it will be essential that the factories still continue to grade the cream and pay for it according to quality. All factories in this respect will be alike, and it follows that should a supplier leave a factory and send elsewhere in view of having his cream graded lower than choice, he may expect similar grading at the next factory to which he sends, unless, of course, the quality of his produce has improved. With the rapid approach of warmer weather conditions, it will be more difficult for some suppliers to consistently receive top grade prices for their cream unless they adopt the necessary measures to ensure that their produce is of reasonably sound quality. The chief faults noticed in the quality of local cream are mainly from a flavor point of view, and are as follows:—

*Stale Flavor.*—Due to keeping cream too long before delivering to the factory, and sometimes bordering on the rancid stage.

*Sour or Over-ripe.*—Due to the presence of too much lactic acid in cream. Warm conditions, low test, combined with age, are all factors tending to increase this trouble. In the course of time a stale and cheesy flavor will usually develop.

*Fermented Flavor.*—May be due to various causes, the chief of which are as follows:—

- (a) Cream kept too long, not in the best surroundings, particularly when it is low in butterfat test.
- (b) Mixing together cream of different temperatures before the warmest has cooled sufficiently.
- (c) Using a separator twice a day, and only washing it once daily, or not scalding the separator parts properly.
- (d) Keeping afternoon milking overnight and heating it up the following morning for the purpose of separating.

*Tallowy Flavor.*—This is a chemical flavor most common during summer months, which can usually be associated with cream of exceptionally high butterfat test. It develops as a result of exposure to heat, or through becoming air dried, and becomes more pronounced with age.

*Metallic Flavor.*—This is another chemical reaction which is usually, though not always, associated with cream of too low a butterfat test. It is caused through the action of the lactic acid in the cream on metal with which it comes into contact. It will rarely occur if the separator parts and other utensils are well tinned and kept thoroughly clean, but once the tinning is defective, or is neglected as regards cleansing, this flavor will soon be noticeable.

It is possible for cream to possess a combination of two or more of the above-mentioned flavors, such as "stale and tallowy," "sour and fermented," &c., all depending upon the conditions under which it is produced, kept, and delivered.

*The importance of frequent delivery to the factory cannot be too greatly stressed, as it is the primary cause of most of the trouble noticed in locally delivered cream.*

The man who desires the best price for his produce will endeavor to keep the cream as cool as possible while it remains on the farm. During warm weather cooling down by any method, but preferably by means of a suitable cream cooler, will greatly enhance the keeping quality, as the bacterial development is considerably checked by reason of low temperatures. Stirring the cream two or three times daily will also assist in reducing any objectionable "feed" flavors that may be present. In all cases, cleanliness plays no small part in the quality of cream, and suppliers who are not in the habit of washing their separators each time they are used are strongly urged to do so.

Rinsing utensils in warm water alone is not conducive to satisfactory results. After being scrubbed and rinsed, all utensils should be thoroughly scalded with boiling water. This latter treatment will tend to eliminate many of the troubles cream is heir to, as it kills all germs which may remain on the utensils, and at the same time the heat ensures rapid drying, and thus prevents the possibility of further bacterial development.

## TOMATO DISEASES IN SOUTH AUSTRALIA AND HOW TO CONTROL THEM

with special reference to Glasshouse Tomato Culture.

---

[By GEOFFREY SAMUEL, M.Sc., Plant Pathologist, Waite Agricultural  
Research Institute, University of Adelaide.]

[Continued from page 510, *Journal of Agriculture*, December, 1930.]

---

### INSECT PESTS.

#### CUTWORMS.

*Description.*—Cutworms are about the first of the insect pests to worry the tomato-grower. However, it is plants put out into the field which suffer most, glasshouse plants being rarely troubled except occasionally in glass-houses on new ground. Cutworm damage is familiar to all growers. The young plants have their stems eaten through about ground level, and flop over and die. Very frequently the cutworm which caused the damage can be discovered if the soil is carefully turned over with a pocketknife round the roots of plants which have been eaten off the previous night. The grub is brown in color and curls round into a circle when disturbed.

*Control.*—The most important point in cutworm control is not to plant on land which has been left dirty and weedy. Where land is worked to its full capacity, with rotation of crops and clean cultivation of soil prior to sowing, cutworm damage will rarely be important. If cutworms are few in number they will be checked sufficiently by the lead arsenate spray advised for leaf-feeding caterpillars. If they are numerous the best remedy is to use a poison bait (see page 633).

#### GREEN CATERPILLARS.

*Description.*—Green caterpillars (grubs) of more than one species eat tomato leaves and bore into tomato stems and fruit. Affected stems will suddenly wilt, and the bore-hole of the grub is easily found at the bottom of the affected part. Fruit is frequently attacked at the stem-end, and drops from the plant, or a soft bacterial wet-rot follows on the grub injury, converting the fruit into a sloppy mess inside the skin.

The caterpillars hatch from small white eggs laid on the plant by moths. After feeding and growing to full size they usually leave the plant to pupate under the protection of rubbish lying on the soil. They then emerge as moths, which fly from plant to plant laying fresh eggs on the leaves and stems.

*Control.*—The control measure to adopt is spraying or dusting with arsenate of lead, but it is much more successful if used early as a preventive instead of being left till the caterpillars have already appeared. It is a good plan to spray the seedlings once in the seedbed, before the leaves have become too densely grown together, and then again soon after they have been set out. As the plants grow, further treatments will be required, and

arsenate dusts will probably be preferable to spray for these later treatments. Treatment in the early stages is easier and cheaper, and will prevent a great deal of multiplication of the pest; it does not then become bad in the later stages as it frequently does when neglected earlier.

#### GREEN APHIS.

*Description.*—Green aphids are so well known that a description of these insects is scarcely necessary. They are usually to be found on the undersides of tomato leaves, or clustered on the young tissue near the growing point of the stem. They suck the juices of the plants, and when numerous they seriously reduce its vitality. They also excrete a sweet liquid, "honeydew," which makes the plant sticky and on which a blackish mould fungus may grow if the insects are very numerous.

Green aphids give birth to living young, and the colony of young ones produced by an adult wingless aphid can frequently be seen clustering round her. No fertilisation by a male is necessary at this stage, and it is only the winged forms appearing mainly at the end of the season which produce the sexual forms that provide for the carrying on of the species over the winter by means of eggs. During the course of their growth aphids shed their skins several times, and in a colony of any size the empty white skins which have been shed can always be seen among the insects.

*Control.*—Control of aphids is best obtained by nicotine and soap sprays or by nicotine-containing dusts. In glasshouse work the dust is most convenient, but the temperature must be above 76° for satisfactory results. In fact, the warmer the better, for the nicotine vaporises more quickly and strongly at the higher temperatures. Dusting with nicotine dusts is therefore best done during the warmest part of the day.

#### THE WHITE FLY.

*Description.*—The white fly, the scientific name of which is *Trialeurodes vaporariorum*, is a well-known pest of glasshouse tomatoes and can cause considerable damage if allowed to multiply unchecked. Even if it does not become bad enough to injure the plants, it may cause considerable trouble by necessitating the wiping of all the fruit.

Three stages of the insect should be recognised by the tomato grower. The egg is a very small white object, hardly visible to the naked eye, fixed to the under side of the leaf by a short stalk; it becomes gradually darker with age, and finally becomes almost black. This stage lasts from eight to 25 days, usually hatching in about 17 to 21 days.

The egg hatches to a small oval scale, which soon settles down to feed on the leaf, sucking the sap and not moving further during this stage of its life. The whitish oval scales are often to be found in large numbers on the under sides of the leaves, and when once known cannot be mistaken. The skin of the scale is cast three times during its growth, and at the end it develops a waxy covering, becomes thicker, and is at a stage corresponding to the pupa of other insects. The winged fly is developing inside this waxy casing, and emerges as the fully formed adult about three to six weeks after hatching from the egg, according to the temperature.

The fragile white adult flies are well-known, flitting about the houses, and live for several weeks. The females may lay from four to seven eggs per day throughout life. During both the scale and the adult stage a syrupy liquid is sprayed out by the insects, which falls on the foliage and fruit and makes them sticky. Often a sooty-mould fungus grows in this

sugary liquid, so that a black mouldy growth covers the plants, and may cause them to become unhealthy by blocking up their breathing pores, and reducing the amount of light falling on the leaves.

The white fly will live on many other plants than tomatoes, and is often especially troublesome on beans. It may therefore be found advisable not to plant beans between the houses.

*Control.*—The white fly is comparatively easily controlled by fumigating with cyanide, but because of the very poisonous nature of the gas a number of growers are afraid to use it. If the instructions are carefully followed, however, there is no danger, and it gives excellent control of the pest.

Control by nicotine dusts can now be done fairly effectively when dusts with the higher percentages of nicotine are used. There is always a danger that many of the flies may be just driven out of the houses before they are killed, however, and, although stupefied for some time, may later recover and regain the plants. If dusting with nicotine is preferred, the treatments should be done at the same intervals as are mentioned below under the heading, "Two fumigations necessary."

Still another way of controlling the white fly is now being tried in England and that is by the introduction of a minute parasitic wasp (*Encarsia formosa*) which parasitises the young scales under the leaves. Very encouraging results were secured in 1928, when some hundreds of thousands of parasitised scales were distributed to growers, many of whom reported complete control of white fly when the wasp was introduced into the houses. Efforts will be made to see if this beneficial insect can be established in South Australia, and thus save the trouble of constant fumigation.

As yet, however, the best and cheapest method for controlling the white fly is cyanide fumigation. A full description of how to do it follows, and this should be read very carefully, and followed in every detail by those who are trying it for the first time. They will find, after doing it once or twice, that the process is so easy that at future times they will have no hesitation in always fumigating with cyanide for the control of the white fly pest.

#### CONDITIONS FOR FUMIGATION.

Fumigation must always be done at night, while the breathing-pores of the plants are closed. It is also advisable to have the plants slightly in need of water, but not so much, of course, that they show signs of wilting. As regards the weather, the only really necessary point is to see that it is not too windy a night, for the type of glasshouse used here is not well closed, and on windy nights the gas would blow out too quickly. It is also better to choose a cool night than a warm one.

#### MATERIALS REQUIRED.

The fumigation is done by dropping carefully weighed quantities of cyanide into small earthenware jars, or glass jam jars, containing measured quantities of water and sulphuric acid, spaced at equal intervals along a centre row of the house.

Glazed earthenware jars about 6in. high can be bought quite cheaply, and about six jars are necessary for every 100ft. of the usual sized tomato house around Adelaide. The method of calculating the number of jars required is described in more detail on the next page.

A measuring glass graduated in ounces, which can be bought at any chemist's or photographer's shop, is used to measure out the water and acid into the jars. The materials are used in the proportions: water, 3oz.; sulphuric acid,  $1\frac{1}{2}$ oz.; sodium cyanide, 1oz. For the size of tomato house usual round Adelaide, 1oz. of cyanide per jar gives a good distribution of gas, so that the preparation of the pots of acid is simple. Three ounces of water are first measured out into all the jars, and then  $1\frac{1}{2}$ oz. of concentrated sulphuric acid (oil of vitriol) are measured out and poured into the water in each jar. The liquid becomes very hot, and care must be taken always to pour the acid into the water, and never water into acid.

The sodium cyanide is weighed out carefully into ounce lots, and each wrapped up in a piece of paper. A small pair of letter scales is advisable for accurate weighing. If lumps of cyanide have to be broken up, do it in a tin or box, so that pieces of cyanide do not become scattered around. Remember that it is very poisonous, and have all tins or other containers labelled cyanide poison and placed out of reach of children and animals. It should always be kept in a closed tin, as it gradually deteriorates in air. It might be possible to buy the cyanide already weighed out in packets. If potassium cyanide is used, 1oz. of sulphuric acid instead of  $1\frac{1}{2}$ oz. is sufficient.

#### MEASUREMENT OF HOUSES.

The amount of cyanide necessary must be carefully calculated according to the volume of the house. The number of cubic feet in a house is calculated by multiplying the length by the breadth by the average height. The average height is found by adding the height of the ridge pole to the height at the sides, and dividing by two. The following is an example of the calculation:—

Find the volume of a house 100ft. long, 15ft. wide, 4ft. high at the sides, and 7ft. at the ridge pole.

$$\text{Average height} = \frac{1}{2} (7 + 4) = 5\frac{1}{2}.$$

$$\text{Volume} = 100 \times 15 \times 5\frac{1}{2} = 8,250, \text{ say } 8,000 \text{ cub. ft.}$$

To cyanide at the rate of 1oz. per 1,000 cub. ft. would need 8oz. of cyanide, which could be used in eight 1oz. packets dropped in eight jars spaced equally along the centre rows of the house.

To cyanide at the rate of only  $\frac{3}{4}$ oz. per 1,000 cub. ft. would need only 6oz. of cyanide, which could be used either in six pots with 1oz. each, or in eight pots with  $\frac{3}{4}$ oz. each.

#### STRENGTH OF FUMIGATION.

The glasshouses used in Europe, which are constructed for artificial heating, are much more air-tight than the houses used round Adelaide, and smaller doses of cyanide, often only  $\frac{1}{4}$ oz. per 1,000 cub. ft. are quite sufficient. With the big gaps along the ridge pole and at the sides of our houses, however, a somewhat larger dose is necessary to be effective. For the grower trying fumigation for the first time, it is recommended that he try the effect of a dose of  $\frac{1}{4}$ oz. per 1,000 cub. ft. first, and if that is found not to kill all the flies and not harm the plants at all, he can increase the dose next time to  $\frac{3}{4}$ oz. per 1,000 cub. ft. Houses vary in air-tightness, and for many this rate will probably prove sufficient, but for other houses, which are poorly closed, 1oz. per 1,000 cub. ft. will not be too strong. Each grower can soon find out for himself the best strength of fumigation for his own houses.

Having seen that the plants are a little on the dry side, and that the night will not be too windy, the pots of water and acid are prepared and set along the houses at equal intervals down one of the centre rows during the late afternoon. The pots nearest the door at each end can be a little closer to the door than the spaces between the pots down the centre to make up for leakage at the ends. The pots will usually be about the width of the house apart. If a very wide house had to be done, two rows of pots might be necessary, in which case two people would be required for the dropping in of the cyanide.

The packets of cyanide are best kept together until just before fumigation begins, which should not be until about an hour after sunset, when it is just getting dark. They may then be either placed along one beside

FIG. 33.—The Brown Surface Mite, *Phyllocoptes lycopersici*, so small that it is just invisible to the naked eye. This mite crawls over the surface of tomato stems and leaves in great numbers, and produces a rusty-colored discoloration and shrivelling of the leaves, working from below upwards.

#### DOING THE FUMIGATION.

each pot of acid ready to unwrap and tip in, or they may be carried along all together in a bucket or bag slung over the shoulder, and one unwrapped as the operator is walking along to each pot, and the cyanide dropped quickly in.

In all cases, the tipping in of the cyanide into the pots of acid should begin at the end farthest from the door, and the operator walk steadily towards the door, tipping the cyanide out of its packet quickly into each pot as he comes to it. He should then close the door and allow no one to go into the house.

The house must be opened and ventilated at dawn in the morning, for if sunlight comes into the house while the gas is still present, the plants are liable to be injured. Open the doors and remove a pane of glass at intervals along the sides to allow the gas to escape, and do not go into the house for a few hours until you are sure that the gas has had time to escape.

The pots should then be picked up and rinsed out carefully into a sink or into a hole in the ground which is filled in immediately. The house may then be closed again, and a watering given if necessary.

#### TWO FUMIGATIONS NECESSARY.

Fumigation kills only the adult white flies and the scales feeding on the under sides of the leaves. It does not kill the eggs, and so a second fumigation has to follow after all the eggs have hatched, but before any have grown to adults and started laying further eggs. The time of this second fumigation depends upon the weather. In hot weather (average temperature in house above  $72^{\circ}$ ) it should follow a fortnight after the first; in medium warm weather ( $65^{\circ}$ - $72^{\circ}$ ) it should not be done for three weeks; and in cold weather (below  $65^{\circ}$ ) only after nearly four weeks. Two fumigations properly done should control the white fly for the whole of the season, provided that white fly are not present on beans or other plants just outside the houses.

Seedlings and young plants in a sappy condition will not stand fumigation to the same extent as older plants which have been topped and which can be allowed to become a little dry before treatment. If it is necessary to fumigate young plants, the dose should be reduced a little. It is evident therefore that the grower who keeps his houses clean, and who is free from white fly during the early months of growth, will have a great advantage over his neighbor who has to fumigate while his plants are still young and sappy.

#### THE BROWN SURFACE MITE.

*Description.*—This disease is frequently called “golden stem.” It usually commences as a discoloration on the stem of the plant, which may sometimes be rather “golden” in appearance, but is usually more dull bronze or rusty brown. The trouble spreads out on to the leaves, which first become rusty brown and then gradually shrivel and die. The disease gradually spreads upwards, working along the stem and out on to the leaves, and finally the whole plant may become shrivelled with only the topmost leaves green, and even these beginning to show the characteristic diffuse bronze appearance of the early stages of attack. The fruit is sometimes affected, becoming bronze in color, and with the surface broken up into innumerable little corky cracks in a fine network.

*Cause.*—The trouble is caused by a minute insect (*Phyllocoptes lycopersici*) belonging to the class of “mites” (Fig. 33). The mites are about one two-hundredth of an inch in length, and so are just invisible to the naked eye except under the most favorable circumstances. They feed and multiply entirely on the surface of the plant, and wherever they are present in any numbers they cause the rusty discoloration. The gradual spread of this discoloration up the stem and out on to the leaves is thus due to the crawling of the mites in great numbers over the surface.

*Control.*—The best control measure is to dust with the finest sulphur dust. Since the mites are soft-bodied and entirely on the surface of the plant, this is one of the most easily controlled diseases. Guard against spreading the trouble from the affected plants to healthy ones by pruning or rubbing against diseased leaves while picking, before they have been dusted with sulphur. Nicotine-containing dusts or sprays are also effective.

## EELWORMS.

*Description*—Although not insects in the true sense of the word, eelworms can conveniently be considered here. They are very minute little worms, invisible or only just visible to the naked eye. They penetrate into the roots of tomato and many other plants, and live most of their life feeding inside on the tissues of the root. The irritation which their presence causes to the plant leads to the formation of knobby swellings on the roots, and when the worms are very abundant these can be so numerous that the whole of the root is thick, swollen, and clubby (Figs 34, 35). In fact, the name "club-root" is sometimes used by tomato growers for this disease.

The presence of the eelworms is usually not suspected until it is seen that there is something wrong with the top of the plant. The plant loses vigor, the fruit fails to set, the leaves are a paler green than normal, and finally become sickly and yellowish.

FIG. 34.—Eelworm lumps on glasshouse tomato roots.

The eelworms in the roots penetrate the tissues in all directions, the females are fertilised by the males, and the eggs then begin developing inside the female body. As many as 500 eggs may be laid by a single female. When the young hatch they may penetrate further into the roots or escape into the soil, where they may swim or be carried in water for some distance and later penetrate fresh young roots.

Eelworms are usually more troublesome in sandy soils. Once soils are infected it is extremely difficult to get rid of the pest, for the eggs can last over the season when there are no plants growing, and the worms can live on the roots of many species of cultivated plants.

*Control*.—Once again, steam sterilisation is the most practical cure for eelworms in glasshouse soil, but unfortunately is not yet available for glasshouse growers in South Australia. The usual remedy practised here is simply to move the glasshouse to fresh soil when the ground becomes badly infected.

A number of chemical treatments have been tried against eelworms with varying measures of success. The grower who notices eelworm infection in a comparatively small patch of his glasshouse may like to make an attempt to eradicate the pest by one of these methods before it spreads through the whole of his house. As soon as the infection is noticed it would be advisable to mark off the area and not allow the water to run across the patch all down the rest of the house if this is possible. The affected plants should be pulled up and the roots burnt as soon as the plants are unprofitable, but the treatment of the soil would best be left until the rest of the house has been pulled out.

Perhaps the most promising treatment to experiment with is the one using calcium cyanamide (Cyanogas). Briefly, the procedure is as follows:—Cyanamide is applied at the rate of 1 ton to the acre ( $\frac{1}{2}$  lb. per square yard) and carefully and uniformly mixed with the dry soil to a depth of 6 inches or more. The soil is then thoroughly irrigated. The treatment should precede the planting of the crop by at least six or eight weeks, during which time the soil should be frequently stirred to break up any crust which may form. The action is essentially a cyanide fumigation, and the residue finally left in the soil is only lime. The efficacy of this remedy has not yet been thoroughly proved under South Australian conditions, however, for it appears to have been used only on rare occasions so far.

#### CURCULIO BEETLES.

*Description.*—Occasionally tomato plants are attacked by Curculio beetles. These beetles live under the soil during the day time and come up and feed on the plants at night. They can usually be found by carefully turning up the soil at the base of affected plants with a pocketknife. They are small brown beetles, somewhat less than  $\frac{1}{2}$  in. long, which usually sham dead when disturbed. They nearly always feed at the edges of the leaves, so that if leaves are seen with the edges all irregularly eaten the Curculio beetle should be suspected.

*Control.*—This beetle can be controlled by arsenate sprays or dusts or by poison baits, as described for green caterpillars and cutworms.

#### SOME DISEASES NOT IN SOUTH AUSTRALIA.

Although nearly 20 diseases affecting tomatoes in South Australia have been described, there are a number of others which have not been found here. Perhaps the most important to mention are Fusarium wilt, and the late-blight or Irish blight which also affects potatoes, for both these diseases are present in other parts of Australia, and may very likely be found here also if favorable weather conditions were experienced.

Fusarium wilt has already been discussed on page 499, December, 1930, issue. Late-blight, caused by the fungus *Phytophthora infestans*, is only troublesome under fairly continuous warm, damp, and muggy conditions, such as are rarely experienced in South Australia. The symptoms consist of rapidly spreading rotten patches on leaves and fruit. Control measures consist of spraying with Bordeaux mixture, combined with general methods, such as rotation of crops (without potatoes), destruction of diseased material after harvest, etc.

As a matter of interest the following other tomato diseases which at times cause appreciable losses in other countries may be mentioned:—

Anthraxnose (*Colletotrichum phomoides*).

Ascochyta blight (*Didymella lycopersici*).

Bacterial spot (*Bacterium vesicatorium*).

Buckeye rot (*Phytophthora parasitica*).

Botrytis stem-rot (*Botrytis* sp.).

Leaf mould (*Cladosporium fulvum*).

Sclerotium blight (*Sclerotium rolfsii*).

Western yellow blight (virus of sugar-beet curly top).

Although some of these, if introduced into South Australia, would probably never become troublesome, owing to the climatic conditions being unfavorable to them (as is the case with the late-blight mentioned above), there are others, such as Leaf Mould, which are certainly to be feared, and it is to be hoped that our quarantine laws succeed in keeping such diseases out of this State for as long a time as possible.

FIG. 35. — Bad Eelworm swellings on the roots of a field tomato plant.

## FUNGICIDES AND INSECTICIDES.

### CHESHUNT COMPOUND.

#### *For Checking Damping-off and Root-rot in Seedlings.*

The mixture is prepared by mixing finely powdered copper sulphate and ammonium carbonate in the proportion of 2oz. of the former to 11oz. of the latter. Ammonium carbonate is in hard lumps, which are rather difficult for the tomato grower to reduce to a fine powder, so that many will find it most convenient to have the mixture made up by a chemist. The dry mixture should be stored in a stoppered glass or stone jar for at least

24 hours before using, and is then prepared for use by dissolving 1oz. of the dry mixture in a little hot water and adding to 2galls. of water. (The solution must not be placed in metal vessels.)

Cheshunt Compound was developed by Dr. W. F. Bewley at the Experimental and Research Station of the Nursery and Market Garden Industries' Development Society, at Cheshunt, in England. It was developed especially to control damping-off fungi in seedboxes. The solution does no harm to the plants (it is advisable not to let it touch the foliage, however, and to hose down with water immediately should any get on the leaves), but it is able to kill damping-off fungi in the soil. In England seedboxes are watered with the solution after sowing, and seedlings after transplanting. In South Australia, with our greater freedom from damping-off troubles, this would rarely be necessary. If seedlings are actually falling over from damping-off, however, Cheshunt Compound should be watered on immediately to prevent the disease spreading to still healthy plants, and it would be advisable to use it again in transplanting.

Cheshunt Compound is always of value where seedlings have to be replaced in the houses because of some root disease.

In the words of Dr. Bewley, "In replacing diseased individuals in the houses the method should be to remove the affected plant, water the hole with a pint of solution, replant with a healthy individual, and again water with the solution."

#### SOIL STERILISATION BY FORMALIN.

##### *For Control of "Damping-off" in Seedbeds.*

Formalin is too expensive to use for soil sterilisation on a large scale, and its use is thus limited to seedbed sterilisation. Here also its use is not likely to be great for some time to come, since the soil of seedbeds can be replaced comparatively cheaply near Adelaide, and soil can be obtained which is practically free from damping-off fungi. There may be occasions, however, on which a grower would like to sterilise his seedbeds thoroughly after some disease has been present, and so the following instructions may be given.

The formalin is used at the strength of 1lb. to 15galls. of water, and the soil is thoroughly soaked with this solution at the rate of about a gallon to each square foot. The soil is then covered with bags for 24 hours, and the bags then removed and the soil aired for at least a week before planting. It is advisable also to sterilise spades, forks, &c., by washing with the solution while there is some made up.

Formalin is a much more powerful disinfectant than Cheshunt Compound, and, therefore, cannot be used once plants are growing in the soil. It can be guaranteed to render soil free from disease, but precautions must be taken that no further disease is introduced in water, on tools, or in any other way.

#### SOIL STERILISATION BY STEAM.

See the article by Dr. W. F. Bewley on "Practical Soil Sterilisation by Heat for Glasshouse Crops" in the *Journal of the Ministry of Agriculture*, Gr. Britain, vol. 33, page 297, July, 1926, or U.S. Dept. Agric., Farmers' Buls., 996 and 1320.

## BORDEAUX MIXTURE.

*For Control of Fungus Diseases of the Leaves.*

Bordeaux Mixture has been largely replaced in glasshouse tomato growing by copper-lime dust, which is really almost a dry Bordeaux dust. These fungicides are the best for checking the spread of Leaf-spot and Early Blight, but since neither disease is widespread in South Australian glasshouses there is no general need yet for copper-containing fungicides in glasshouse work here. Tests will have to be made later on the relative efficiency of Bordeaux Mixture and the copper-lime dust in checking Early Blight under our conditions, and any grower whose plants are suffering from Early Blight might well compare the two treatments.

Bordeaux Mixture is made of—

4lbs. copper sulphate (bluestone).

4lbs. lime (fresh and good quality).

50galls. water (rainwater, or good quality).

This mixture (4-4-50) is somewhat weaker than the standard (6-4-50) which is often used on outdoor plants. The copper sulphate dissolves most easily when tied in a bag and suspended near the top of the water, or it may be dissolved in a jug of warm water and then stirred into the cold. The lime should be gradually slaked and stirred into an even paste and then diluted to a milky fluid. The best Bordeaux mixture is made when the bluestone and lime solutions are equal in amount (in two non-metal vessels, e.g., small barrels) and are run simultaneously into a third lower vessel (a larger barrel) through a fine brass wire or muslin sieve. Under these conditions the mixture forms the finest possible precipitate which will remain in suspension well while spraying. It should be sky-blue in color, and not green, and it should not deposit any copper on the blade of a bright pocket knife dipped into the solution.

## NICOTINE-SOAP SPRAY.

For the control of tomato spotted wilt, in order to kill the black carnation thrips on seedlings in the seedbed or on plants not long put out, it may be found preferable to use a nicotine-soap spray instead of a dust, since at the time of year the temperature is scarcely high enough to vaporise dusts well.

The nicotine-containing sprays on the market are either extracts of tobacco plants containing pure nicotine, or a 40 per cent. solution of the chemical compound nicotine sulphate, as in Black Leaf 40. Full directions for use are usually given on the containers. It is advisable always to use soap with these sprays and to make them up with rainwater if possible. Thrips need fairly strong solutions to kill them, and a 1 in 800 solution of Black Leaf 40 is the weakest which will be effective. Some growers have used 1 in 500 with no damage to plants, and better results.

## DUSTS.

Dusts are widely used in glasshouses now in preference to sprays, for the conditions are almost ideal for their application. The absence of wind means that the cloud of dust hangs in the air round the plants and deposits a fine film of the fungicide or insecticide all over the surface, reaching positions in a fairly dense foliage where it would be almost impossible to get a spray. This is most important, for the whole principle of applying a fungicide is to cover the healthy plant completely with a poisonous

coating, which will kill any fungus spores which germinate on the surface. Similarly, in the case of an insecticidal dust such as an arsenate, a covering must be put over the whole plant so that wherever the young caterpillar hatches from the egg and begins to feed it will be unable to eat the leaf without eating some arsenate as well.

All the dust manufacturing companies now supply combination dusts, containing both fungicidal and insecticidal substances. Copper and sulphur are the chemicals used against fungus diseases; an arsenate is the chemical used against chewing insects; and nicotine the chemical against sucking insects (*see page 622*). Combining them all makes a dust which is of value against all above-ground pests and which is very little trouble to apply. A number of growers dust regularly with one of these proprietary dusts as an insurance against disease, and this is probably the safest method for the grower who does not feel confident that he can quickly detect diseases.

Dusts are by no means inexpensive, however, and the man who knows his diseases well and who is also careful in removing diseased plants can save money by dusting less frequently. *Under our conditions at least two treatments are usually necessary for the proper control of green caterpillars. One of these should be soon after the seedlings are established in the houses, and the second just before the flowers on the first truss open. It is quite a good plan to make these two standard dustings, and to use a combination arsenate-nicotine-sulphur dust (or a proprietary "tomato dust," which contains copper in addition and is slightly more expensive).* These two treatments should greatly reduce the chance of any pest multiplying up during the season, provided the houses and their surroundings are kept properly clean.

It is not suggested, however, that the grower should *rely* on these two dustings to keep his plants clean. He must be continually on the watch for fungus diseases or insect pests, and immediately apply a dust if one is seen to be spreading. In such a case there is no need always to use the most expensive combination dust, however. It may be that caterpillars are the only pest which is not being controlled, and a plain arsenate dust would be the logical dust to apply. Even when two or more pests are multiplying a suitable combination dust to control both of them can always be chosen from the trade catalogues. A few examples may make these points clearer. Should a grower notice a few plants infected with the Brown Surface Mite (Golden Stem) he would immediately get the dust gun and dust these few plants and a few surrounding with sulphur, for this pest is easily killed with sulphur, and it can scarcely spread through the house at all unless it is carried on the hands or the clothes of workers. Should there be noticed a number of plants with the dark spots of Early Blight on the leaves, however, the grower would first go along and nip off affected leaflets and take them out and destroy them, and then dust the whole house with a copper-lime dust. Dusting the whole house is advisable in the case of Early Blight, for fungus spores are so light that they can spread in air currents. Had aphids been noticed on some of the plants at the same time as Early Blight it would have been advisable to use a copper plus nicotine dust instead of a copper alone. These are just a few examples of how dusts can be chosen to suit each particular case. The correct dust to use for each pest (provided that a dust will be of use) can be found in the paragraph on Control which follows the description of each particular disease.

One or two cases have come under notice where the application of a copper dust at flowering time has affected the setting of the fruit. Further

investigation will be required to determine under what conditions this may occur. Another point which needs investigation is the relative merits of copper carbonate and copper-lime (bluestone and lime) dusts under the conditions in our glasshouses. Some of the proprietary copper-containing dusts contain their copper only in the form of copper carbonate; and this may not prove to be as efficient a fungicide as the copper-lime. At all events, for the present, if a fungicidal dust is needed it is suggested that preference be given to the copper-lime dust, and that it be not applied at the time of maximum flowering of any truss, if this can be avoided.

#### FUMIGATION WITH CYANIDE.

See page 622 (Control of White Fly).

#### POISON BAITS FOR CUTWORMS, ETC.

There are numerous formulas for poison bait. They all contain an arsenic poison such as Paris green, white arsenic, or London purple mixed with a bulky substance such as bran or slack lime, and with a sweetening or attractive substance such as sugar, molasses, oranges or lemons, or amyl acetate added.

A typical formula is as follows:—

Bran, 20lbs.

Paris green, 1lb.

Treacle, 2qts.

Five finely chopped oranges or lemons, or  $\frac{1}{2}$ oz. amyl acetate.

Water, 3galls.

The Paris green is thoroughly mixed with the bran first, and then the whole moistened to the desired degree with the sweetening mixture. If the bait is to be spread over a large area it is preferable to have it almost dry and sprinkle it along the rows of plants. About 6lbs. per acre is all that is required for outdoor use where the plants are 3ft. apart.

#### CLEANSING THE GLASSHOUSE AT THE END OF THE SEASON.

Especially after a fungus or insect pest has been prevalent it is desirable to thoroughly cleanse the glasshouse at the end of the season. Some growers burn sulphur in the houses, but while this is valuable it has not proved entirely satisfactory in all cases.

In England Dr. Bewley recommends the use of an emulsion of cresylic acid and soft soap. (This is practically a crude home-made Lysol). Dr. Bewley gives the following directions for preparing the emulsion:—Pale straw-colored cresylic acid and pure potash soft soap are placed in a bucket at the rate of 1gall. of the former to 8lbs. of the latter. The bucket is then heated over a brisk fire until all the soap is completely dissolved, the process taking about 10 minutes to complete. This strong emulsion is used at the rate of about one part in 50 parts of water, *i.e.*, 1 pint in 6galls. The diluted emulsion is best applied with a strong power sprayer, and should be carefully directed into all cracks in the woodwork, and over the glass, the surface of the soil, in fact everywhere. The house should then be closed for several days, and later opened and aired for two weeks or more before planting. It is advisable to wear goggles and rubber gloves while spraying.

A simpler, but not quite so efficient, method is to spray with strong lime-sulphur solution instead.

(Concluded.)

## ERADICATION OF YACCA (*Xanthorrhoea Semiplana*.)

[By ROWLAND HILL, Agricultural Instructor.]

Throughout the South and South-East of this State, as well as on the lower end of Eyre Peninsula, there are tens of thousands of acres that could be developed as excellent pasture lands, providing the cost of clearing could be reduced. In many cases *Xanthorrhoea semiplana* (the low-growing yacca) has been responsible for the major portion of costs of clearing. In the South-East and South 30s. an acre has been the usual contract price for clearing the land of such growth by grubbing, and where the growth was exceptionally thick the cost has been considerably in advance of this figure.

When completed, the method of clearing by grubbing is not always satisfactory on account of the great depth of some plants and their liability to shoot again.

The type of Yacca being dealt with on Mr. F. J. Summers' Property at Back Valley.

Various methods of treating the yacca with the idea of cheapening the cost of eradication have been carried out, but the work done by Mr. F. J. Summers, of Back Valley, near Luman Valley, in conjunction with the Vacuum Oil Company Proprietary Limited, is certainly outstanding at present. Accompanied by Mr. L. A. Wilde, of the Vacuum Oil Company, and Mr. W. L. Summers, Secretary to the Minister of Agriculture, I inspected these tests on Thursday, December 12th. Mr. F. J. Summers has every reason for being enthusiastic on the results he has obtained.

### TREATMENTS.

Pure Laurel kerosene, which can be purchased in 40gall. drums at 1s. 1½d. per gallon at the Adelaide depot, was used in all cases.

#### Treatment A.

This trial comprised an acre of scrub land which contained 960 yacca plants. With an old teapot, kerosene was poured into the heart of each plant on July 8th, 1930. The operation took one man two and a half hours, and 8galls. of kerosene were used.

The result was at least a 90 per cent. kill. The cost of treatment would be about 4s. 6d. per acre for labor and 10s. for 8galls. of kerosene, at, say, 1s. 3d. a gallon. The total cost would therefore be 14s. 6d. per acre under this method.

*Treatment B.*

On July 25th two additional acres were treated. One of these contained 401 yaccas and the other 409. The kerosene was applied in the same manner as in test A. No record of the time of labor expended was kept, but the quantity of kerosene used was 1½galls. for the two acres, whereas 8galls. were used to obtain the same result in test A with 960 yaccas, only 1½galls. were needed for two acres and 810 yaccas in this test. As the results in test B were equally as effective as in test A, it plainly shows that in the latter far more kerosene than necessary was used.

Mr. F. J. Summers with a tea pot and adze used for treating plants. He has in his hand the centre of a Yacca which has been easily pulled out three weeks after treatment.

*Treatment C.*

In this case all leaves were cut off level with the ground with an adze and the kerosene then applied. This saved much kerosene, as it could be easily directed to the correct spot. Cutting them off in this manner also acted as a guide, showing which yaccas had been treated. An area of three-quarters of an acre, containing 665 yaccas,

was cut and treated with kerosene by one man in two hours and twenty minutes on October 3rd. Four gallons of kerosene were used, and the result was 100 per cent killed. With kerosene at 1s. 3d. a gallon on the spot this method can be successfully carried out at the cost of 12s. per acre.

Yacca stumps lifted out by plough three weeks after treatment showing the hollow centre which has decomposed.

According to these tests, that in C is certainly to be recommended. The quantity of kerosene and time needed per acre will, of course, be governed by the number of yaccas present. From the results of treatment C it seems reasonable to accept the figure of 150 yaccas to 1 gall. of kerosene, and the possibility of a man treating 240 to 300 yaccas an hour. This is certainly more effective than the grubbing method, and is only one-third of the cost.

Yaccas growing on sandy land were treated as in treatment C and ploughed three weeks later, with the result that all the yacca stumps turned up easily with the furrows, the centres being in a state of decomposition.

Mr. Sumners informed me that a mid-summer treatment would probably take more kerosene, because the sap is then rising and the plant harder to kill.

It was very noticeable that clover and other feed plants growing right against the treated yaccas had not been affected in any way by the kerosene applied to the yaccas.

## THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

## FORTY-FIRST ANNUAL CONGRESS.

[Continued from page 498, *Journal of Agriculture*, December, 1930.]

[Papers read at the Men's Congress on Wednesday, September 17th, appear elsewhere in this issue.]

**Tuesday, September 16th.**

## CONSERVATION OF FODDER.

Mr. E. H. FISHER, of the Wasleys Branch, presented the following paper:—

A large number of farmers in South Australia do not give this very important matter due consideration from a farmer's business point of view. Farmers seem to think that when one drought has gone, no more will follow for some considerable time, but that is not so; history always repeats itself. And now that the present drought has broken, the time is opportune to put aside a reserve stack of hay. This in a bountiful year does not involve much expense, because when hay is plentiful it is cheap. The interest lost directly on that reserved stack while good years continue would not amount to many pounds, but the value of that amount of capital invested would be many times doubled when a drought occurred. I consider a stack of hay on hand a good "probate policy for a drought."

Of the hay fodders, we have wheaten hay which should be cut a little on the green side. Stock will then eat it more readily, and, when in the stack, mice will not touch it so much. Oaten hay should not be cut too green, because it has a tendency to be bitter. I do not recommend this as a reserve fodder, because if cut in the golden tinge and stacked, mice in a short time would destroy the whole stack. It should be put in the bottom of a wheaten stack and on no account used for roofing purposes.

Barley hay, preferably Cape barley, may be cut with advantage and put aside when too rank to be left for reaping for grain, and fed to stock, preferably loose.

## STOOKING.

I favor the "lying down" stook, which, if properly made, will keep out a considerable amount of rain. This method of stooking preserves the color and weight of the hay and makes the sheaves nice and flat for stacking. With 30 to 36 sheaves in a stook, placed butt to butt, it takes a fair amount of wind to disturb them.

A stack of sheaved straw is of great assistance in dry years. If properly stacked it will keep indefinitely without spoiling, and if mixed with good wheaten hay will materially augment the fodder supply of the farm.

## STACKING.

The site chosen for the stack should be on high land. First of all put down a good layer of straw about a foot thick all over the ground which will be the size of the stack. The shape matters very little; round end stacks are quicker to build on the ends than square corners, but square corners are better for opening and tying on the roof. When the shape and the size of the stack have been decided upon, go to the middle and stand the sheaves up the same as if a standing-up stook is to be made, and work that stook out until it is the size and shape of the stack. This prevents any of the heads of the sheaves from touching the ground. Build up the walls to about 16ft. to 18ft., keeping the middle of the stack not less than 3ft. higher than the walls. The roof should be built with butts on the outside filled in behind the heads out.

Another fodder that can be saved is "cocky chaff," and, if put in a heap and covered with a good coat of loose straw, will keep for many years. It can be fed with molasses and will make an appetising feed for stock in times of want.

#### ENSILAGE.

Last, but not least by any means, comes the fodder which I consider is absolutely essential for a dairying district and which can be of great assistance in many ways to any farmer, and that is ensilage. Ensilage is the cheapest form of reserve fodder available, because when crops are too rank, especially stack yards where manure has been spread, the crop can be cut in its green stage and yield about 6 tons to 10 tons to the acre, but if left for hay would not be worth much. Over 90 per cent. of farmers in the past have not given this fodder any consideration. I think this is so because they do not know the value of its succulent qualities. It has many advantages over other fodders; it can be kept indefinitely for years and come out of the silo equally as good as when put in. This cannot be said of other fodders, because the longer they are kept the more they deteriorate, and there is no loss with fire. In dry years, high prices tempt farmers to sell as much hay as they can, but this is not the case with ensilage. It does not command a ready sale on the farm, therefore the stock benefit, and they relish ensilage in the summer months of the year because its succulence is as good as green feed. It is just as good for mares with foals, ewes with lambs, and sows with suckers for producing milk for their young as it is for dairy cows giving milk.

There are several ways of storing this fodder. The methods are silos built above the ground, stack ensilage, and pit ensilage. I consider the pit method the cheapest, especially if an underground tank or two is available. Chaffed up it can be taken out as required with ease in bags. After the tank has been filled, it is necessary to put loose straw and heavy weights on top to exclude all air. Finally, the pit should be covered with a roof to keep out the wet, as rain spoils any form of fodder.

---

#### Wednesday, September 17th—Morning Session.

##### WHEAT GROWING.

Mr. H. G. FISHER (Tatiara) contributed the following paper:—

In these days of high cost of production the farmer must get good yields to make wheatgrowing pay, especially on the better class of soils, and this is the land my paper refers to mainly. Nothing should be left to chance. The land we intend fallowing for wheat should be in a good fertile condition to produce a good crop; if not, it should be sown to oats or peas or top dressed heavily and left to pasture or sown to Subterranean clover in the districts with good rainfall, to enrich it for the coming wheat crop. My experience in working land extends over 28 years. The soil is of a loamy character and is farmed on the three-course system (fallow-wheat-oats) with an occasional year to pasture and a crop of barley grown in place of oats after a few years. The oat crop sown on the burnt wheat stubble ground has been as payable as the wheat crop, considering the less work that it takes. Of course, our district has the benefit of the Melbourne market, which is always about 6d. a bushel above Adelaide prices. Growing oats helps to keep the land free from take-all.

Our Agricultural Instructors recommend a system very similar to the one I have worked on for years and find it works out in practice very well. I would like to point out that oat crops in this locality are not so good as they were in the earlier cropping periods. They do not appear to be obtaining just what they need from ordinary superphosphate dressing, and we are now waiting for the scientist to come along and tell us what they need. Only by the scientist and the farmer working together can we ever hope to get the best from our land. While the oat crops have not been so good, the wheat crops have yielded more on this system. Last year one of our paddocks averaged

between 14 and 15 bags per acre after being cropped on the three-course rotation for the last 25 years, and the whole wheat crop of between 300 and 400 acres averaged 36bush. per acre. This serves to prove that, acting on advice from our Department of Agriculture, that a liberal dressing of super and fair working of the soil, the land will stand continuous cropping for a long period.

Some of the essentials of producing a good crop are fallow early, especially in the drier districts. For fallowing I favor the mouldboard plough, turning all grass and rubbish well under to decay; then leave the land lay for a few weeks if the weather is good, but if heavy rains fall it must not be left too long or it will set hard and not work up nice and even. The first cultivation must be fairly deep, practically to the bottom of the plough, which should be about 3½in. on average soils. This working deep at the first cultivation helps to break up the furrows and consolidate the seedbed. Also it hastens the germination of weed seeds, a great factor in producing a clean crop. The cultivators must be kept going when weeds appear above the surface, except in the driest of weather, when sheep will be found very beneficial to keep the fallow clean. Working the fallow when weeds are small retains the surface mulch and leaves the seedbed intact.

When the fallow is ready for sowing, go over it once more; it will always pay. As regards time of sowing, every farmer should know what has proved the best time in his district. Farmers should keep records of the date of sowing their crops and then they would have practical experience on their own particular farm and sow according to experience. My experience leads me to prefer a later sowing than the general rule, but if a farmer has low-lying land in the heavy rainfall districts, he must get it in early to get a good germination. Only sow deeply on those occasions when it becomes necessary to put down the seed into the moisture to get a good germination. Quantities—I recommend 75lbs. of graded seed and 150lbs. of super per acre on the good soils of our State with a fair rainfall. Sow the variety of wheat that has given the highest yields over a period of years in your own district. If sowing seed of your own crop, save it from the cleanest part and from wheat harvested in the middle of the day for preference, because in the morning the thresher is generally close down and the germination of the grain might be affected. Never sow any but the best of seed. If there is ball smut in the crop obtain fresh seed from the College or a farm you know, and order early.

Method of doing the Work.—Some people claim that tractors will beat horses; I doubt it. I have had experience on our farms where we work two eight-horse teams and a tractor, and I think the horses are the cheapest. The tractor can get over a vast amount of work just at a critical period, and makes farming more pleasant, one factor in stopping the drift to the city.

In conclusion, we should use our practical experience on our own particular farms, and, with the aid of the scientist and our Agricultural Instructors, I see no reason, in a fair season, why we should not be able to produce a good crop of wheat.

---

### Wednesday Afternoon.

### FREE PARLIAMENT.

The following resolutions were carried:—

Mr. A. Smith (Bugle) moved and Mr. Ebsary (Bute) seconded—"That in view of the keen competition overseas, and in order to improve our standard of saleable wheat, we believe that the adoption of the system of branding of wheat bags similar to that in operation of Western Australia would prove advantageous to South Australian wheat growers."

"That we consider it advisable to introduce legislation similar to the Wheat Bags Act, 1928, now in operation in Western Australia, and that all wheat be marketed on grade instead of the present F.A.Q."

Mr. L. Dinning (Mundalla) moved and Mr. A. Ross (Mundalla) seconded—"That instructors of the Department of Agriculture be allowed to judge at country shows."

On the motion of Mr. H. Fisher (Tatiara), seconded by Mr. Butler ( ), it was decided—"That judges have power to award prizes in fallow competitions without taking moisture content."

Mr. Johnson (Yeelanna) moved, and Mr. M. Gardner (Koppio) seconded—"That representation be made to the Hon. Minister of Agriculture requesting that the Crop Competition subsidies be continued."

The following resolutions lapsed:—"That this Congress is in favor of awarding the State Cup for Crop Competition to the farmer who receives the highest points according to the rainfall during the growing season." "That the registration of bulls be abolished." "That the Crown Lands Department compel farmers in new land to leave three chains of standing green scrub on the south and east side of block or holding, if necessary passing legislation to give this effect." "That in the interests of economy all Bureau Conferences be abandoned for one year." "That at Conferences the agenda paper be strictly adhered to for time and subjects."

---

## WOMEN'S SESSION.

### Tuesday Afternoon.

#### HOME NURSING.

Mrs. W. VARCOE (Millicent) read the following paper:—

So many women and girls nowadays are required to do some home nursing that a few hints here may be found helpful.

Keep your patient as far removed from kitchen odors as possible. Never wear creaking shoes or a rustling gown when caring for the sick. The home nurse should learn to take the patient's temperature, pulse, and respiration. The temperature of a person in normal condition is 98.25 degrees, and any deviation from this, either higher or lower, indicates that all is not as it should be. If the temperature is much higher or lower than it should be something is radically wrong. Any doctor will instruct the home nurse in the use of the clinical thermometer. Never take the temperature immediately after a sick person has taken either very hot or very cold liquids, as this prevents getting the correct degree; neither should the thermometer be used directly after a meal, as eating and drinking tend to elevate the temperature. Take it at about the same hour each day.

To count the pulse, place the tips of the fingers on the inner underside of the wrist, and when able to feel the pulsation of the artery plainly, count the beats for a minute—to yourself, of course. The normal pulse of the average adult is usually 72; though, in different people it may be as low as 60, or as high as 80, and yet be normal. In children the pulse beats much faster than in grown people.

In counting the respirations, do so without the knowledge of the patient, as to audibly count a person's breathing will render him incapable of doing so naturally. Normally the respirations are from 18 to 22 per minute, though these may vary, but if below 12 or above 30 there is serious trouble.

Do not allow the sick person to know just what temperature the clinical thermometer registers every time it is used. If the patient inquires, an evasive answer can easily be given if the nurse possesses tact.

Do not keep asking the patient how he or she feels, and never under any circumstances discuss the condition of an invalid in his presence, either by questioning the doctor or retailing the symptoms to anyone else. Do not be uncertain as to which medicine you administered last. If your memory is poor write it down, or the sick one

will worry as to your reliability in the handling of drugs. If you have anything to say to a person in the sick room other than the patient say it clearly, and never in the irritating half whisper that many use when talking to the sick.

In changing sheets on a bed, and this should be done daily if the patient is feverish, turn the patient on one side. Stand on the side away from the invalid. Fold the blanket and upper sheet carefully over on the patient. Pass to the other side of the bed, and roll the other sheet towards the invalid. Place the clean sheets on this side of the mattress, rolling the part that will go under the patient. Gently roll or assist the patient over to that side of the bed on to the clean sheet, and in this way the old sheet can be removed and the new sheet unrolled and put into place. If you can get assistance, let one person sit on the end of the bed and hold the patient while you shake the pillows and put on new covers. The change in posture often rests the patient.

In giving nourishment follow the advice of the attending physician closely and strictly. Where it is ordered every hour, or oftener, give on the minute, unless the patient is asleep when the time comes, in which event do not disturb him unless particularly ordered to do so, for sleep is nature's most potent remedy in many cases.

When a patient has so far convalesced as to require solid foods, do not trouble him with questions as to what he would like, but try to provide some little surprise at each meal, as this often stimulates the appetite. Remember that a quick, tepid soda bath, besides being wonderfully refreshing, will reduce the temperature of a feverish patient, and that after a nap, or to induce the same, sponging the hands or face in methylated spirits and water, turning the hot pillows or substituting fresh ones, gently brushing the hair, or stroking the hands slowly will often soothe and quiet.

Rest is as important for the nurse as the patient. She should manage to go out for a short walk every day for the air and change, and where there is more than one member of the family available the night should be divided into watches, that each nurse may get an undisturbed sleep of three or four hours. Whatever the illness, all superfluous articles of furniture or clothing should be banished from the sick room, that the air may be as fresh and sweet as possible. An open fireplace affords ideal ventilation, but lacking this a narrow board fitted into the lower part of the window answers very well—thus allowing the air to draw up between the two sashes without the danger of direct draught. No dishes, spoons, or glasses should be allowed to stand after being used. All dust should be removed from floor and furniture each morning by the use of a dampened cloth, wringing it out frequently in fresh water. Add to these rules tact, unlimited patience, and strict obedience to the doctor's orders, and you have a good chance to "pull" your patient through any ordinary illness.

---

#### PREPARATION AND CURING OF BACON.

The following paper was read by Mrs. C. PHILLIS (Parilla):—

It is advisable to kill for bacon in the colder months of the year, and practically the whole of a pig can be used.

Let us assume that a pig of medium size, about 150lbs. to 200lbs. in weight, is killed and cleaned in the usual way, and is left to hang on the gallows for about 24 hours to set. A good chopper, a saw, and a sharp knife are required. There are two ways to saw the pig—first saw downwards, from the tail to nose; second, cut the bones each side of the backbone and take the whole of the backbone out in one piece. Cut off the head close behind the ears. Cut out the flat pieces of lard from the ribs. Saw off the trotters—hind ones just above the hocks and front ones just above the knee.

Cut off the hams, leaving the sides as long as possible for bacon. Cut off the shoulder close to the shoulder blades. Shape the hams and take out the bone to the socket, nicking off the socket knob with the saw. This helps to cure the bone of the ham. Bone the shoulder and leave it in one piece to cure as bacon, or cut it up into pieces of meat to pickle or roast. Cut out the rib bones from the bacon sides and level off the fleshy pieces of meat. These pieces can be used for sausages. This completes cutting up one half of the pig. Treat the other half in exactly the same manner.

#### CURING.

To make brine, obtain a clean pickling cask, and sprinkle a thick layer of salt in the bottom. Put into a pan about 6lbs. of salt, 3lbs. brown sugar, and  $\frac{1}{2}$ lb. saltpetre. Mix this well together and rub each piece of meat thoroughly with the mixture. Pack the meat into the cask, fleshy part upwards, and put the bacon sides on top of the other meat. Allow it to stand for about three days, then drain off the brine and turn the meat. Make another brine by filling a petrol tin bucket three parts full of water. Dissolve into it as much salt as will float a fresh egg. Add the brine previously taken off the meat and bring all to a boil, skim off any scum that may arise and allow to stand overnight until quite cold. Next day pour it over the meat, which should be turned over every day. The bacon should be left in the brine for about a fortnight, the hams a little longer. To dry, salt it and pack it away into suitable box, use the same salt and saltpetre and a little pepper and not so much brown sugar, say 1lb., as for making a brine. Rub each piece of meat thoroughly with the mixture. Lay in a box, fleshy part upwards, rubbing the meat about every three days. Leave in pickle for about a fortnight—hams a little longer. Then take them out and rinse off the brine in cold water and allow it to drain for a day or two.

To roll the bacon beat the sides out flat with a rolling pin and sprinkle a little sugar, pepper, and spice, if liked, over the meat side of the bacon. Then roll up tightly, using a buckled strap to keep it in position. Put several coils of strong bacon cord around the rolls, about 1 $\frac{1}{2}$ in. between each strand, and make half-hitches to keep the cord from slipping, and tie securely.

It is a good plan to rub over the bacon rolls and ham with olive oil to keep the rind soft, as it is easier for cutting. Sprinkle hams with a little pepper. Bacon and hams may be smoked in the usual way.

My method of dealing with the smallgoods is as follows:—Take the head of the pig and cut off the cheeks and tongue, rub these with salt and put them into the pickle; then chop the headbones into about six pieces, after taking out the eyes and chopping off the nose. Put them into a dish with salt and water and allow them to stand for a day, then make brawn by putting it into a saucepan with clean water to cover. Season with pepper and salt and thyme; boil until all the meat leaves the bones. Remove the bones and put the brawn into a basin to set. When cold it will be quite firm to cut. The brains are very nice fried. The trotters are usually put into the pickle, but may be added to the brawn. Thoroughly clean the sausage skins and put them into salt and water for about three days, changing the water each day. Mince all the pieces of meat that have been cut off when shaping the hams and bacon. Add the kidneys and heart and season with salt, pepper, and thyme and sage. Mix these ingredients well together, and fill the sausage skins; divide into lengths and fry in the pan. The lard must be rendered and put into a jar to set, covered over, and kept in a cool place. The ribs, neck, ham, shoulder bones, and backbone may be roasted or used in many ways.

Under the guidance of Mr. E. H. Fromen (Manager), delegates inspected the dairy and farm produce factory of the S.A. Farmers' Co-operative Union at Mile End.

## POULTRY EXPERT.

### APPOINTMENT OF MR. C. F. ANDERSON.

Mr. C. F. Anderson has recently been appointed to the position of Poultry Expert, after having held that office in an acting capacity since the retirement, in April last, of Mr. D. F. Laurie, with whose work he had been in close touch for a number of years. He received his first appointment in the Department of Agriculture in 1909, and in 1924 was appointed Manager of the Parafield Poultry Station and Assistant Poultry Expert. Under his charge, the Parafield Station was remodelled, and is now a modern poultry plant with an established business in the sale of fertile eggs and day-old chickens throughout the State. Prior to Mr. Anderson's appointment at Parafield, the day-old chicken trade was unknown in South Australia. The Parafield sales of this

class of chicken now amount to 12,000 a season, and besides this, the Station disposes of a similar number of fertile eggs. There is an average stock of 4,000 birds, and, in addition, a Single Test Egg-laying Competition is conducted there under Mr. Anderson's supervision.

Mr. Anderson considers that the rapid increase in our overseas egg exports is largely due to the systematic work and instruction of the Poultry Section of the Department. Commercial poultry farming has become an established business proposition in South Australia, and the export trade has doubled during the past twelve months.

For many years Mr. Anderson has been actively interested in the educational side of his work. The Parafield Station has afforded an excellent medium for the distribution of information on the latest methods of chicken-raising and poultry management. An average of 800 people visit the Station each year for the purpose of gaining first-hand knowledge of the work of that institution. In this way, Mr. Anderson has been

able to impart useful information to representatives of the commercial poultry farmers, members of branches of the Agricultural Bureau, poultry project clubs, beginners in poultry keeping, officers of the Education Department, as well as interstate and overseas visitors. He has also given addresses on poultry matters to poultry clubs, project clubs, and Branches of the Agricultural Bureau. He has attended many important Conferences in other States in the interests of the egg export trade, including the first Interstate Conference of Commercial Poultry Breeders which was held in Sydney in 1926.

Amongst other activities Mr. Anderson has contributed articles to the press for the welfare of the poultrykeeper and with the object of stimulating interest in this important section of our rural industries.

---

## OUTBREAK OF PSEUDO-POULTRY PLAGUE IN VICTORIA.

---

Mr. C. F. Anderson (Government Poultry Expert) recently visited Victoria to inquire into the disease which has occurred in poultry flocks in that State. He reports that Dr. H. E. Albison, of the Veterinary Science School, at Parkville, Victoria, has definitely identified the disease to be "Pseudo Poultry Plague."

It is not known how the disease first originated in Victoria, but it is assumed that the disease has been imported from overseas, either by the introduction of poultry or cage birds, because the disease has never been previously known in Australia. The severity of the disease and the seriousness of the position can be realised when it is realised that the mortality is 100 per cent. of the affected birds. There is no known cure for the disease.

It is certain that only the stringent action taken by the Victorian Department in placing the whole State in quarantine, and closing up all auction rooms, had checked the spread of a disease which threatened to entirely wipe out the poultry industry, not only in Victoria, but also in the adjoining States.

The Victorian authorities are now definitely of the opinion that the outbreak is under control.

The symptoms of the disease are:—Loss of appetite; crouching attitude; sleepiness; the eyes being half closed; watery, yellowish-white diarrhoea, with a characteristic nauseating odour. The crop is distended with a sour-smelling, greyish-brown fluid. The most marked symptom is the gasping inhalation through the half-opened beak. Most cases have a thick, mucous discharge from the nostrils and a varying amount of frothy exudate in the mouth, which occasionally hangs in threads from the end of the beak. The comb and wattles vary in color from dark-red to purple. These symptoms are followed by death in from five to seven days.

### PRECAUTIONS IN THIS STATE.

Owing to the very serious nature of the disease, stringent precautions are being taken to prevent the spread of the disease to this State; besides the heavy losses that would occur in stock, our export markets would be closed, for once the disease spread to South Australia we would be in quarantine, and no live poultry, dressed poultry, or eggs in the shell would be allowed to leave the State. This would be the ruin of our poultry industry, owing to South Australia being such a large exporter of eggs and egg pulp.

Action has been taken under the Stock Diseases Act to prevent the importation from Victoria of any poultry, ducks, geese, turkeys, &c., and also the eggs of such birds. Very close supervision is also being kept on overseas steamers against the introduction of birds from overseas, unless accompanied by proper certificates.

*In view of the seriousness of the disease, the closest co-operation of poultry breeders with the Department is urged, in the matter of reporting immediately to the Department any signs of sickness among poultry, when the trouble will be investigated.*

## BEES AND BEEKEEPING.

[Paper read by Mr. ARNOLD E. OPHEL, Middleton, at a meeting of the Mount Compass Branch of the Agricultural Bureau.]

Considering the many thousands of years during which honey-storing or hive-bees have been known, it is somewhat surprising that the average person has so little authentic knowledge of their habits. The one thing which seems generally known is that they can sting, and perhaps an exaggerated fear of this defensive action is responsible for the slight acquaintance with other more interesting points in their behavior.

My own early lack of knowledge and experience of bees was probably typical. I recall an occasion when a fellow-scholar was stung by a bee, and when we hurried to the school with a fearsome childish impression that the boy would surely die suddenly. The schoolmaster was, however, an enthusiastic amateur beekeeper, and we were given a series of lessons on bees. We were shown diagrams of the sting—the two hollow, barbed shafts which, when inserted into the skin, were so operated by a set of muscles that each point was alternately driven deeper and deeper while the poison flowed through the centre. The schoolmaster then caused a bee to sting the palm of his hand so that we could watch the operation. It was demonstrated that when a bee stings it usually tears itself away, leaving a little bunch of muscles and poison gland attached to the sting, and these muscles continue working until the poison is all pumped into the flesh. For this reason, it is advisable, if possible, to scrape off quickly the tiny white speck showing on the skin, and thus avoid receiving all of the poison. It should not be picked off, as the operation will only squeeze in the poison. If not too frightened, a bee will save its sting after injecting the poison, by whirling around and unwinding the sting, corkscrew fashion, out of the flesh—the barbs preventing it being directly withdrawn.

There are a few people whose systems react in exceptional ways to insect poisons, and bee stings may produce in them unusual swellings and rashes. The average person, however, suffers no serious effects—only a sharp burning sensation for a few minutes and perhaps a certain amount of puffiness and tenderness for a day or so. A beekeeper usually protects his face when at work because of his eyes, for admittedly this is where trouble might occur, but elsewhere stings cannot be very serious, seeing that he may receive dozens of stings in the course of a day's work (if the weather is unfavorable), and yet he can seldom locate one of them after a short while. We soon learn that the tendency of bees to sting is defence and not offence, which they seek to show, though there are some types which seem naturally more irritable than others.

This brings us to a consideration of the different races of bees and their peculiarities. Incidentally, it may be mentioned that there are many kinds of bees which are not hive-bees. Many species are like small flies and wasps (our own native bees are mostly of this type), and they do not live in large communities as do the hive-bees. They are of interest mainly to the scientist, but their connection to the bees with which we are familiar is seen in the four wings which fold down when at rest, whereas flies have only two wings—a notable example being the hover fly seen on flowers or above them with wings outstretched, and often mistaken for a bee. Native bees also play a part in the pollination of flowers, but probably of less importance than the hive-bee, because they are not such persistent gatherers, having no occasion to store up any quantity of this valuable nitrogenous food—often called bee bread.

## BREEDS INTRODUCED TO AUSTRALIA.

Australia has no hive bee of its own, though the black bee common throughout the coastal belt of the continent is usually referred to as though it belonged here. This black bee, which is a native of Europe, was first brought to New South Wales in 1822, and so favorable were the conditions that it rapidly spread through the coastal areas. It is not found in Central Australia, however, an arid belt of country having proved a barrier to its migration to those favored portions of the interior where the native bees thrive in abundance. During the '70's" and '80's" quite a number of Italian bees were brought to all the States, also a few Carniolan and Cyprian bees. These were all very distinct species, from different countries of the Old World, and doubtless, it was considered, might be useful for crossing with the black bees which had their weak points—being irritable, rather too easily discouraged in a poor season and not very resistant to disease.

The Cyprian bees were good workers but in temper were as fiery as their color and little breeding was done with them. The Italian proved quiet, thrifty, and hardy, and this yellow-banded race quickly established itself a favorite. The Carniolan dropped into the background without a thorough trial, apparently, perhaps, because in color they somewhat resembled the black bees already here. In recent years interest was revived in the Carniolan and they have been found to possess some very desirable qualities, especially for a changeable climate like ours.

Possibly the time will come when we shall have evolved a type of bee most suited to our climatic conditions, but it will take a time to fix a type where so much mixed stock is already to hand. It is considered that the bee of Northern Italy—known as the Ligurian—was gradually evolved from crossing the German black bee with the bright yellow bees of the Mediterranean area. By a process of selection, the present type eventuated, and having been bred in that country for hundreds of years, the characteristics are now so fixed as to be practically a separate race.

The German bee may have in the remote past been taken also to the little country of Carniola, surrounded by the Julian Alps, and, if so, the process of selection has been carried on in that isolated country so long that a distinct race appears to have resulted, superior to the original black bee in every way. The Alpine climate has hardened the constitution and developed thriftiness to a notable extent, while the gradual discarding of the more irritable stocks has, in the course of time, strengthened the peaceable tendencies, until to-day the general run of the stock is such that veils are unknown in Carniola and smoke is not used, unless it be a puff from a cigarette to induce the bees to move out of the way of the fingers while working.

## COMMERCIAL BEE-KEEPING.

Although honey-storing bees have been known and honey appreciated by human beings as food since the dawn of history (and probably before, for references may be found in the oldest writings), bee-keeping as we understand the term is of comparatively recent development. It is rather interesting, however, to note that many crude forms of domestication—if one may apply that term to a free flying insect like the bee—have been known for centuries and are still used in some parts of the world. Ideas were borrowed from the habits of bees themselves and short lengths of hollow trees were set up for the bees to carry on their work; this in turn suggested clay cylinders and other more or less portable vessels as places in which the honey might be stored and be better available than in the trees and hollowed rocks. In Cyprus cavities are often left in the walls of gardens, and swarms placed in them, so that the householder may help himself to their stores when he feels inclined.

But true domestication in the sense we apply the term to animals and birds is unknown. A colony of any of the races of hive-bees taken from tree or rock will make itself at home; and with equal unconcern a colony whose forbears have lived for 50 years in man-made hives will "go-bush" and be at no loss to themselves.

In Australia the ever useful kerosene case is the most common form of primitive hive, into which the bees cluster and build as the spirit moves them, and it has the disadvantage of all primitive methods wherein the bees build the combs to suit themselves. Knowledge of the condition of these colonies is largely guesswork, and disease may easily secure a footing before the owner is aware of it.

Movable combs made commercial bee-keeping possible, and while the fundamental principle is simplicity itself, many intricate patterns of hives were evolved before the Rev. Langstroth gave to the world the idea upon which practically all modern hives are made. Bees are comparatively exact in their habits, and it was noted that to ignore these habits in designing a hive made it unworkable. All parts to be moved must have a bee space (approximately 5/16in.) left round them, for where bees cannot crawl they plaster up with wax or a gumming substance called propolis, which they collect from various plants and trees. Similarly, if they are given more room between movable parts than they require for passing, they will in time fill up the unnecessary spaces, possibly with a lining of cells adapted to suit the cavity. For bees, marvellously exact as they seem to be, are really more wonderful in their manner of adapting the general principles of comb building to the circumstances in which they find themselves. The familiar design of six-sided cells, fitting so exactly to each other without loss of space, has for ages been looked upon as the ideal of strength, beauty, and economy, but they build two sizes of cells, one giving 28 to the square inch and the other 18. The smaller is for rearing worker bees, the larger for drones and for storing honey—though the smaller cells may also be storage cells for honey and pollen when not required for brood. Now it is the merging of one size into the other and the fitting of either or some intermediate size into odd spaces which best shows the wonder of their workmanship.

HAVE YOU SEEN THE NEW MODEL 1930

**ALFA LAVAL**

There are 10 New Improvements, including  
Ball Bearing.

Rust Proof Bowl, Rust Proof Discs,  
Trailing Skim Milk Discharge from Bowl.

Year by year the ALFA LAVAL has led the way—each New Model has been by far the Best Separator in its day, but the 1930 New Model is far ahead of anything ever made before.

Free Trial. Specially Easy Terms.  
It will pay for itself.

## THE INHABITANTS OF THE HIVE.

## THE QUEEN.

This difference in cells leads us to note some details regarding the bees themselves. In a hive or colony will be found, under normal conditions, three kinds of bees—one queen, many drones, and many more worker bees. Given sufficient room and prosperous conditions, they may reach a total of 100,000. The queen is the mother of the colony and, while she is all right, no further queens are permitted until they are preparing to send out a swarm, in which case there will be a number of peanut-shaped cells showing in various places in the combs. These cells first show as little cups—like acorn cups, in each of which the queen lays an egg, and they are then lengthened as the grub which emerges from the egg grows. These grubs are fed on a very rich pre-digested food prepared in a portion of the digestive system of the worker bees, known as the chyle stomach. This organ is most active in the younger bees up to about five or six days old, and they are therefore known as nurse bees, for they feed this food to *all* young grubs for the first day or two of growth, weaning all but the queens on to some mixture of honey and pollen, the drones receiving a coarser preparation than the workers.

Only the queens receive the chyle food, usually referred to as "royal jelly," during the whole period of larval development and they become perfect females. All worker bees are females, but their maternal organs are undeveloped, though under stress of need, as when the colony has been queenless for a few weeks, any worker is liable to produce a few eggs. The queen is fully developed in this respect; therefore, her body is much larger and longer than that of a worker. The workers are sometimes wrongly called "neuters," because they do not mate. The queen alone has the impulse to mate, and the act occurs while on the wing, normally some time between the seventh and tenth day after emerging from the cells. When mated, she then becomes just an egg machine; a remarkable one, too, for when conditions are right she is capable of laying several times her own weight in eggs in 24 hours—rather a staggering performance. Obviously, feeding plays an all-important part in this matter. Some richly-nitrogenous, easily-digested food that passes immediately into her system must be fed to her almost continuously during the active laying period, which may continue for weeks. Possibly she is supplied with a substance similar to royal jelly, upon which she was reared.

The queen differs in other respects from the workers, having neither the brush-tongue for collecting nectar from flowers or the honey-sac for storing it, or the curious receptacles on the rear legs for carrying pollen. The comparatively enormous loads which are carried make intelligible the phrase "as big as a bee's knee."

Once egg-laying commences the queen does not mate again, nor does she leave the hive, unless the colony becomes prosperous enough to cast off a swarm, when she goes out with a portion of the bees to form a hive elsewhere, leaving a young queen to carry on.

The thousands of drones which they are prompted to raise in the spring is Nature's prodigal way of providing for the survival of the race (and the fittest), for only one drone is required for the young queen; but when thousands are flying from each colony the chances of inbreeding are reduced to a minimum. Moreover, the young queen flies strongly and far, and only the strongest of the drones will overtake her.

## THE DRONE.

In following the history of the drone we stumble into what is surely one of Nature's most astounding miracles. The drone is the son of his mother only; in other words, a queen can lay drone eggs even if she is not mated—a phenomenon known as parthenogenesis. When mated, she lays worker or drone eggs at will, according to the size of the cells in which she deposits them. There is no outward difference in the eggs, but those impregnated by the male element produce females, those not impregnated produce

males. While every worker egg contains a potential queen—that is to say, it could be developed into a queen if fed with royal jelly and its cell suitably enlarged—nothing will modify the development of the drone. He is destined to live his useless, defenceless life, dependent upon the charity of the working community for his very existence, on the off chance that he, among the many thousands taking their daily midday flight, may meet a mating queen and pass on his mother's characteristics to posterity through her.

Nature is ruthless even in this matter, for the drone dies in the act of mating; and, should prosperous times pass quickly and the danger of shortage of stores occur, the workers unhesitatingly drive all the drones out of the hive, where they must perish, for they cannot gather food outside even if it were there. Should a queenless hive be near, many will find sanctuary, because the workers there are always hopeful of raising a queen and recognise the possible need of drones, so therefore tolerate them at all seasons.

Since drones live on the honey and pollen gathered by the workers, they are expensive to rear and maintain, and the beekeeper does what he can to prevent large numbers being raised by providing the bees with comb foundation containing only worker cells. Flat sheets of this foundation fastened into wooden frames induce the bees to build combs that are convenient to handle and economical to use.

#### BUILDING THE COMB.

Beeswax is a product of the bees' bodies, formed in tiny scales between the segments of the abdomen when the bees are gorged with honey and hot as a result of clustering closely together. To watch bees comb-building is a puzzling affair. A bee takes a tiny scale in its jaws and threads it this way and that, clamps it over the edge of a partly-formed cell wall, gives it a bite or two, and then apparently gets tired of the job and goes off. Another takes her place and "fiddles" round a while, and leaves it, and so they are continually coming and going in a seemingly haphazard fashion, yet all the time the work proceeds by imperceptible stages over the face of the comb—the wall edges always showing a rounded finish. The amount of weight which this tissue-like substance will carry is surprising. Melt a piece of natural comb containing a pound of honey and the wax will only amount to about half an ounce.

The queen and drones take no part in comb-building, and it is likely that the process of secretion is a heavy drain on the system of the worker. But building in any quantity only occurs (in their natural state) during periods of prosperity conducive to heavy brood rearing, which more than makes up for wastage of the stock. There is something wonderfully consistent in the operations of a colony, dovetailing one into the other so well. Plenty of food, more bees; more bees, more work; more work, more wastage—but more bees to take their place.

#### THE WORKER.

The life of a worker bee is short in most cases, a matter of a few weeks at most when there is work to be done. The greater the activity, the shorter the life; wear and tear of wings and of the internal organs soon renders them unfit to carry on, and realising this they usually crawl away from the hive if possible when they feel the limit mark has been reached. Autumn-raised stock will live through the winter if there is little activity of the colony, though in this country a certain amount of brood rearing is often carried on through a mild winter if the bees are kept snug and warm. In countries where snow occurs it is usual to winter all the bees in cellars, where they go into a state of complete inactivity.

Drones are longer lived than workers when conditions are favorable enough to allow of their continuance, and commercial queen breeders make provision for saving desirable kinds over the winter in order to secure earlier matings than would be possible if it was necessary to wait for spring drones. Taking 24 days to hatch, it is approximately 40 days from the laying of the egg until the drone takes life seriously, and the colony must first attain a prosperous condition before it prepares for drones.

Worker bees are flying to the fields in 28 or 30 days after the eggs are laid, and they meanwhile have done duty for several days in the hive as nurse bees, having hatched on the 21st day.

#### BREEDING AND HEREDITY.

A queen may take her mating flight 20 days from the egg, hatching as she does on the fifteenth or sixteenth day. Her life may be four or five years, though from a commercial point of view she is seldom worth retaining as the head of a producing colony after the second year. She started life with a certain number of eggs in her ovaries, and after a couple of active laying seasons may not be able to maintain the colony at productive working strength. If a colony shows up exceptionally well in the amount of honey produced and there are no undesirable qualities about the stock, it may prove worth while retaining the queen for breeding purposes for a year or two longer (in a small hive where she will not be tempted to outlay herself). Though, as a matter of fact, unless she is purely bred herself it is doubtful whether she would throw true to type.

The laws of heredity have to be reckoned with in breeding bees as in other creatures, and these are added difficulties, because the mating cannot be controlled. A breeding queen is selected on the characteristics of the colony she has raised—productiveness, combined with a reasonable docility in handling, and evidence of a hardy constitution being sought, with regularity of the size of the body and markings of the workers as an indication that she may be expected to produce her like in other queens. Of course, just what the progeny of the other queens will prove to be depends upon how they mate. But in any case, they will produce drones of the same strain because, as already pointed out, the drone is unaffected by the mating of his mother.

Commercial breeders seek an area where the queens can have, say, a two mile flight before reaching drone stock other than that retained by the breeder for the purpose, and he may expect to get a fairly high percentage of the mating he wants. In practice, it usually pans out that in a few years all stock flying within reach of the breeder is so permeated by his strain that very few mis-matings occur. Should he endeavor to build up a strain by selection and crossing, he must seek complete isolation for the mating stock—a somewhat difficult proposition, for bees sometimes inhabit unexpected places. They have been found in rabbit burrows, hollow fence posts, and other queer places where trees were not available.

#### LEGISLATION.

In the early days of Italian importations, sufficient interest in this matter was taken by the Government to have Kangaroo Island declared a sanctuary for Italian bees.

Our State has been backward in the matter of protective legislation and inspection. At the present time, of course, the financial stringency is sufficient to hold it up, but we, who are dependent upon bees for our living, have waited for some definite attempt to be made to cope with the trouble; we are always fighting individually. Surely it is no more right that, through the carelessness of some people, the special diseases of bees should be allowed to ravage the country any more than swine fever or fruit diseases should go unchecked. Nobody desires to hinder his neighbor from keeping a few colonies as a sideline, but if they are allowed to die out or are neglected they become a menace to others, and if they are kept in ordinary boxes, where inspection of the combs is impossible, they are likely to be a menace at any time.

As with other primary industries, seasonal conditions provide sufficient difficulties and uncertainties without adding those which are the outcome of carelessness, though I am rather inclined to think it may be lack of knowledge as much as anything.

We have progressed quite a long way from the days when it was thought necessary to brimstone the bees to rob their stores. We are ahead of those times when boxes were turned upside down and the bees drummed up into another while the combs were

cut out and squeezed into a muslin bag to dip out their contents, which sometimes included the juices of mashed up bee grubs, clean enough in themselves, but hardly likely to improve the flavor of honey.

#### EXTRACTION OF THE HONEY.

Our frames of comb are now placed in wire baskets and whirled round at sufficient speed to throw out the honey, and are then returned to the hives to be used again. Honey flows are not always of long duration, and the great thing is to keep the bees storing all the time it is available. Their natural tendency is to fill up the storage space and then sit back. On the other hand, if they had to be continually rebuilding comb, as in the old way of working, considerable honey would be consumed and time wasted in the process.

## If you can't grow vegetables

*and you can't buy them, you will  
certainly need a stock of Swallow  
and Ariell's Compressed Vegetables.*

**T**HEY'RE equal in every way to fresh, as only water is removed—true flavour is retained. One pound goes as far as ten of the fresh, so that they're easily carried. Store them as long as you like—with a few packets at hand you need never be short of health-giving vegetables.

### Here's the Range of Compressed Vegetables.

Carrots, Parsnips, Turnips, Onions, and mixed—Compressed and supplied in  $\frac{1}{2}$ lb. cartons and 1lb. tins.

Tomatoes and Rhubarb—Compressed and supplied in  $\frac{1}{2}$ lb. cartons.

Beetroot—Loose, in 1lb. tins.

Mixed Vegetables—Loose, in  $1\frac{1}{2}$ oz. packets.

# SWALLOW & ARIELL'S COMPRESSED VEGETABLES

From the extractor, honey should be placed in clearing tanks for a few days to allow particles of wax and pollen to rise to the surface, to be skimmed off. A gentle heating of the honey to about 120 degrees hastens the production of a clear, bright article for the market.

Should the honey show at any time any signs of fermentation it indicates that the bees had not completed their part of the business when it was taken. Nectar as it comes from the flowers is quite different chemically from honey—it is just like a sweetened water and will ferment readily. The bees not only evaporate a large proportion of the moisture, but certain secretions of the honey sac, into which the nectar is taken up many times after it reaches the hive, gradually resulting in changing its chemical condition—a process known as sugar inversion. When the bees have finished with it they seal it over in the comb, and when extracted at that stage it may be said to keep indefinitely, though it is wise to exclude air from it if stored for any length of time, for it has the property of absorbing considerable moisture. Most honeys show more or less granulation after a time, and is then known as candied honey; this is no real detriment, and it may safely be liquified by standing the vessel in hot water and rendering slowly.

#### HONEY AS A FOOD.

Honey occupies a unique position in Nature, and I think the ancient peoples realised its value more than we do to-day. No other food passes so rapidly into the blood stream, for it can be assimilated unchanged, only requiring dilution to allow absorption to take place. Although it has no tissue-building value, it is a rapid energy-producer, as most beekeepers have had opportunity of proving. The mineral content of honey also makes it a most valuable item in the food of growing children, and a prominent doctor of Victoria has stated that the greater part of teeth decay would disappear in the next generation if every one used even one teaspoonful of honey every day in their food. It sounds a small thing to lead to so great a result, but the daily portion would build up a deficiency of our systems which our civilised habits in food have to account for. Probably other troubles would disappear or be lessened, too, if everyone had a daily spoonful of this natural tonic.

#### MARKETING PROBLEMS.

Apart from health considerations, I know one thing it would cure, and that is the marketing problem—for, as in every other primary industry, there are difficulties in securing a reasonable return to the producer when the market is glutted in a good season. On the whole, we have the largest exportable surplus of any of the Australian States, and interstate trading makes it necessary to consider the Commonwealth as one market when discussing this question. If every family in Australia used 2ozs. of honey every day, they would absorb over 25,000 tons per year—which is more than we produce.

It would be rather curious to become importers, but while I doubt that the need will ever arise, it is not because I think we could always produce that quantity. It is not unlikely that the future will bring to many beekeepers the problem of where to get sufficient honey to make their calling worth while. In this State most of our table honey comes from red, blue, and pink gum, and the wholesale cutting out of these timbers has already seriously depleted the areas available for bees. Most land owners seem to think that once the axe starts, everything should go—which seems a pity, because there is reason to believe that a certain amount of timber left would be an advantage rather than otherwise.

In a country like New Zealand, where so many varieties of clover thrive, beekeeping has expanded with the larger areas laid down as pasture. The advantage has not been one-sided either, for the bees assist the sheep and dairy men in securing good stands of clover by ensuring satisfactory pollination. Unfortunately, few portions of this country are suitable for the heavy honey-producing clovers, such as White Dutch, Strawberry, and Alsike.

## RED COMB EGG ASSOCIATION.

## OFFICIAL SINGLE TEST.

## EGG-LAYING COMPETITION, 1930-31.

Conducted at the Parafield Poultry Station under the Supervision of the Department of Agriculture.

Total No. of Pens.—Section 1. White Leghorns—204 birds; Black Minorcas—3 birds.  
Section 3. Black Orpingtons—30 birds. Section 4. Rhode Island Reds—6 birds.

Twelve Months Test. To start on April 1st, 1930.

Section 1.—White Leghorns, 1 to 204; Black Minorcas, 205 to 207.

ORCHARD NOTES FOR SOUTHERN DISTRICTS,  
JANUARY, 1931.

[By CHAS. H. BEAUMONT, District Horticultural Instructor].

The main work for the month is the harvesting of the soft fruits. So far no improvement has been noticed; ripe and firm fruits are packed in a bushel box together and considerable loss is sure. Good fruit deserves careful packing. There will be few apples available for export, and every effort should be made to keep them of the highest quality; the fact that we have a small crop does not necessarily mean that anything will sell well, because there is plenty available in other States. This month should be the latest for irrigating. The control of codlin moth will be difficult, and the work of spraying will need extra care; those who are intending to use white oils should be careful to do the work in the early hours of the morning or on a cloudy day. Spraying of any kind may do considerable harm if carried out on a hot, sunny day. Curculio beetle is vigorous this year and must be checked or there will be a bigger number left for next year. Use arsenate of lead, strong dusts, or 1lb. of powder in 8galls. of water. This may be used on roses with best results. Orchardists troubled with woolly aphis should get the *Aphelinus mali* to work for them; most of the orchards have them now, and there should be no difficulty in procuring them.

Vines should be watched for oidium and downy mildew, especially if showers continue. Our usually dry climate has made us almost immune from downy mildew, but we are still liable to an attack should the weather become showery; the remedy or preventive is well known and is easily applied.

Young trees and vines should not be allowed to suffer from want of water. The soil should be loosened after irrigation and weeds kept down.

## DAIRY AND FARM PRODUCE MARKETS.

MESSRS. A. W. SANDFORD & CO., LIMITED, reported on January 5th, 1931:—

**BUTTER.**—Since our last report the production of butter throughout the State has rapidly declined, and with consumption keeping up fairly well it has necessitated the importing of considerable quantities of choicest from the Eastern States. The London butter market has shown improvement during the last few weeks, and some of the later shipments from South Australia will benefit thereby; but except for the lower grades the season for exporting overseas is now finished from here. Values have firmed in this State, and at present are:—Choicest creamery fresh butter in bulk, 1s. 5½d.; prints and delivery extra; second and third grades, 1s. 3½d. (these prices are subject to stabilisation levies); best separators, 1s. 1d. to 1s. 3d.; well-conditioned store and collectors', 11d. to 12d. per lb.; heated and pastry, 10d.

**EGGS.**—As with other produce, the seasonal decline in quantities was noticeable in eggs, and, unfortunately, the quality at the end of the season is always adversely affected with the heat. More care is necessary in the counting and testing to effect sales, as a big proportion of the consignments is affected by staleness at this time of the year. Ordinary country lots, hen 5½d. per dozen; duck 6½d. per dozen; selected and infertile higher.

**CHEESE.**—The supplies of cheese are keeping up well, but the local and Western Australian demand is sufficient to clear all stocks, so that fair quantities are going into cold store for winter use. New makes, large to loaf, 6d. to 6½d. per lb.; semi-matured and matured, to 11d. per lb.

**ALMONDS.**—Fairly heavy quantities were marketed just prior to Christmas, but have since declined. Demand was well maintained, but has now eased. No change in prices was recorded. Brandis, 7½d. to 8d.; mixed softshells, 7d. to 7½d.; hardshells, 4d. to 4½d.; kernels, 1s. 6d. to 1s. 6½d. per lb.

**HONEY.**—Stocks of honey held in this State are heavy, and with the new season's "take" now being marketed in increasing quantities, the outlook is somewhat obscure. Sales are very limited, and all wholesalers and tinnerns are holding large stocks. Prime clear extracted in liquid condition, 3½d. to 3¾d.; best quality candied lots, 2½d. to 3½d.; second grade, 1½d. to 2d.

**BEESEX.**—Unaltered; 1s. 4½d. to 1s. 5½d. per lb., according to sample.

**BACON.**—Much better trade in bacon and hams was done at Christmas time than was anticipated, and many curers were unable to supply the whole of the orders for hams, so that considerable numbers were imported from the other States at the last moment. Since Christmas, however, the trade has shown an easing, and ample supplies are now available for all requirements. Best local sides, 9½d. to 10d.; best local factory-cured middles, 9d. to 9½d.; large, 7½d.; local rolls, 9½d. to 10d.; Geo. Farmer's "Sugar Cane" brand hams, 1s. 2d.; local hams, 1s. to 1s. 1d.; cooked, 1s. 3d.; "Sugar Cane" brand lard in packets 11d., in bulk 10d. per lb.; local lard, 10½d. per lb. in prints.

**LIVE POULTRY.**—The quantity of birds marketed this year was not so great as in other years, and it is probably due to the fact that farmers have retained laying hens to a greater extent than usual so as to obtain an income from the eggs. Since Christmas the numbers marketed have been very short, and we anticipate that a good demand will rule, as there is a steady demand maintaining. Prime roosters, 4s. 11d. to 6s. 3d.; nice-conditioned cockerels, 3s. 6d. to 4s. 9d.; fair-conditioned cockerels, 2s. 9d. to 3s. 4d.; chickens, lower; heavy-weight hens, 3s. 4d. to 4s. 3d.; medium hens, 2s. 6d. to 3s. 2d.; light hens, 2s. to 2s. 5d.; couple of pens of weedy sorts lower. Geese, 5s. to 6s.; prime young Muscovy drakes, 5s. to 6s. 6d.; ducks, good conditioned, 3s. 9d. to 4s. 9d.; ducks, fair conditioned, 2s. 3d. to 3s. 3d.; ducklings lower. Turkeys, good to prime condition, 1s. to 1s. 6d. per lb. live weight; turkeys, fair condition, 9d. to 11d. per lb. live weight; turkeys, fattening sorts, lower. Pigeons, 6d. each.

**POTATOES.**—New Western Australian Delawares, 5s. 6d. per cwt.

**ONIONS.**—Best white, 5s. per cwt.

## RAINFALL TABLE.

The following figures, from data supplied by the Commonwealth Meteorological Department, show the rainfall at the subjoined stations for the month of, and to the end of December, 1930, also the average precipitation to the end of December, and the average annual rainfall.

| Station.                          | For Dec. 1930. | To end Dec. 1930. | Av'ge Annual Rain-fall. |

## AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

### REPORTS OF BUREAU MEETINGS.

#### SOUTH-EAST DISTRICT.

MILLICENT WOMEN'S (Average annual rainfall, 29.70in.).

October 17th.—Present: 16 members.

Interesting reports on the Annual Congress were submitted by Mesdames Altschwager and Varcol.

**DIETS IN THE HOME.**—Mrs. L. Oberlander read the following paper at the meeting held on November 21st:—"Water is an essential factor in the daily diet. It has several functions to perform, one being to flush out the system and to remove impurities from the blood. It is a good plan to commence the day by drinking a glass of pure water, and to drink between meals, and also to have a glass of water last thing at night on retiring. I have practised this habit nearly all my life, and can testify to the fact that it has not done any harm, whatever the benefits derived may be. One cannot lay down a fast rule for all to follow as regards diet—some people suffer distress on partaking of eggs or oatmeal, while too much sugary or starchy food is possibly bad for others. It is, therefore, essential to have a reasonable balance in the diet of proteins and fats. If vegetables and fruit are used in the daily diet a normally healthy person should benefit accordingly."

#### RENDELSHAM.

September 6th.—Present: 14 members.

**CARE OF THE LAMBING FLOCK.**—Mr. C. Faehrmann read the following paper:—

"During the gestation period (which is from 140-147 days in the ewe), as with all pregnant animals, the main food needed by the ewe is proteins and mineral salts in order to meet the body formation and requirements of the young lamb. Proteins build blood, nerve, brain, bone, muscle, wool, hoofs, &c.; mineral salts, bodily heat and fat. Ewes deprived of proteins will rob their own body systems to supply the needs of the young lamb. The result of this is unhealthy lambings, dead lambs, loss of ewes at lambing, poor milk supply in ewes, and consequently malnutrition or loss of lambs before weaning. During the gestation period and after lambing a daily ration of about 2ozs. of linseed sheep nuts (linseed cake broken into nut form) to breeding ewes increases lambing percentages, makes lambs stronger constitutionally and better able to withstand marking and attacks of disease, enhances the milk flow in ewes, and also aids wool growth. *Percentages of Lambing.*—Our lambing figures do not compare favorably with those of Great Britain, where the average sheep-farmer expects at least 100 per cent., and often reaches 150 per cent., while many of the flocks average 120 per cent. year after year. These figures are the more striking when we compare our weather conditions with those of England. Our season is in mild or warm weather, while that of Great Britain is about freezing point. The English methods entail much more labor than is generally necessary with Australian flocks:—1. The English-bred ewe is more prolific, therefore we should endeavor to breed crossbred ewes to get best results. 2. The English farmer is more particular in the use of sufficient rams and more readily rejects old and stale rams. 3. He arranges shelters for lambing ewes and has a shepherd in constant attendance. This shows that certain precautions are necessary to avoid needless losses. *The Care of the Ewe.*—Ewes should be handled with great care. Do not allow badly-bred and badly-trained dogs to rush the sheep about. A good quiet dog will help to quieten the sheep and should be trained to work well out of the flock. Any rough animal should not be used. *Lambing Paddock.*—It is a good plan, if possible, to arrange for a field near the homestead for a lambing paddock. The paddock should be well grassed, with native pasture for preference, well drained, and dry and clean underfoot. If possible, windbreaks should be in existence. Planting of trees on the windward side of the paddock, and, in fact, all of the stock paddocks should have breaks planted for the comfort of the stock generally. Usually, it is advisable to divide the flock before

lambing, picking the ewes which are likely to lamb early. The picking of sheep heavy in lamb can usually be done by feeling the udders of the ewes. At the same time, great care should be taken not to roughly handle the ewe when doing this. Under our conditions it is not usual to have a man specially engaged for care of the lambing ewe, nor is it absolutely necessary. With the paddock as close as possible to the homestead and the services of a good back, one man can usually attend to 500 ewes in about three hours, providing the weather is mild. He should go around the flock twice a day, keeping a sharp look out for ewes which are about to lamb. It is not wise to interfere too early, as Nature will right itself, and damage is often done by interfering. It is much wiser to leave a ewe and return to her an hour or so later. *Assisting the Ewe.*—If assistance is required, it should be done with care. The normal presentation is the forefeet, followed by the nose, and with this, little difficulty is experienced. Often, however, presentation is at fault, and then difficulty arises. Should any great difficulty be encountered, the lamb should be gently pushed back into the womb, turned around, thus correcting the position, and then, as in normal cases, proceed to gently draw the lamb downwards and outwards. It is a cruel procedure to attempt to draw a wrongly presented lamb, and should, therefore, be avoided. Experience will teach a man thoroughly. Nature provides plenty of room for the turning of the lamb in the womb, and hence little difficulty will be encountered if this is done. Cleanliness must be observed, and it is a good plan to anoint the ewe with carbolic oil. If a ewe will not take the lamb, a good plan is to tie her up or pen her in a small yard with the lamb. Perhaps the ewe will have to be held for the lamb to obtain a drink. Another good plan which has proved successful is to smear the lamb with the ewe's milk and also smear the ewe's nose with her own milk, to which a little bran has been added, to the lamb and the ewe. A motherless lamb may be placed on a ewe which has lost her lamb by adopting the above methods. During rough weather it is advisable to carry a small bottle of olive oil or a small bottle of brandy. Often a little olive oil will revive a weak lamb. Bringing a lamb into a warm room will often help to revive it. Should the ewe be lost, it is a good plan to thoroughly wash the lamb in a bath of water at a temperature of about 103 degrees and thoroughly dry and wrap in a warm covering. As the lamb does not get the 'colostrum' milk of the ewe, the nearest approach is cow's milk—half pint fed through a bottle and teat. Add to the cow's milk one teaspoonful of sugar and the white of one egg per day to supply the extra albumen that is in the colostrum milk of the ewe. Lambing pens have been found useful in wet districts. A yard one chain square is large enough for from 200 to 300 ewes. This yard should contain a small haystack, where the ewes will be able to nibble and also keep themselves dry underfoot. Lambing pens also encourage ewes to feed from troughs should this be necessary. This shelter should prove useful on the farm for other stock during the part of the year when not used for lambing. *Tailing Lambs.*—This should be done while the lambs are young. It is not advisable to wait until all the lambs have been dropped, especially if the lambing is a protracted one. The best age is about two weeks. *Tailing.*—The knife—this is quickest and easiest and the stump heals more quickly than after the searing-iron. There is some risk, however, of the lamb bleeding to death. Much bleeding can be prevented if the lambs are tailed in cool weather and the flock should be rested both before and after tailing. The searing-iron stops bleeding almost entirely. It has a tendency to cause a scab, and does not heal so quickly as the knife. The iron should be kept at an even heat; a white-hot iron will often injure the bone with fatal results. Lambs should be done young. Another method is to cut with a knife and sear the main artery with the iron. This stops bleeding without forming a scab. Earmarking should be done at the same time as tailing, and every farm should have a distinctive earmark. Ewes and lambs should be pastured on some prepared crop of either rape or barley. It is advisable to change the paddocks as often as possible, i.e., daily instead of, say, once a week. A good plan is to let sheep feed on ordinary pasture through the night and morning and turn on to, say, rape in the afternoon. This allows them to gain much more feeding value. Care should be exercised in the detection of scouring, and if such should occur, concentrates, such as crushed barley or oats, are helpful. If a lamb is to be sold at four to four and a half months it is much better to sell direct from the mother. If the object is to sell a 50lb. to 60lb. lamb, which means holding the lamb for six months, then weaning is probably the better method." Mr. Faehrmann also read a paper on the keeping of pigs as a side line. (Secretary, Mr. F. White.)

TINTINARA (Average annual rainfall, 18.78in.).

The monthly meeting of the Branch was held on August 30th, there being present 10 members and visitors. Mr. E. S. Alcock (District Agricultural Instructor) delivered an address, "Top Dressing and Fodder Conservation." (Secretary, Mr. B. Fotheringham.)

## UPPER-NORTH DISTRICT.

## (PETERBOROUGH AND NORTHWARD.)

APPILA-YARROWIE (Average annual rainfall, 15.01in.).

September 5th.—Present: 15 members and visitors.

THE PRODUCTION OF PROFITABLE SHEEP.—Mr. W. Lange contributed the following paper:—"There are few countries in the world so dependent on primary products for their livelihood as Australia. Nevertheless, it is a well-known fact that the Australian wheat is regarded as one of the finest milling wheats produced anywhere in the world. Having this distinction, with the aid of favorable circumstances and improved farming methods, it should next be our aim to raise the products of our pastures to a similar extent at a reasonable cost of production. This would mainly represent wool, beef, and fat lambs. To achieve this aim of both quality and quantity, from our restricted rainfall areas, we should first direct our attention to improving the breed and then the feed, as these are two of the main factors leading towards success. A well-bred animal requires little more feed than a weedy one, but the return value is almost double.

*Usefulness of Various Breeds:* Merinos should be grown for quality of wool, have a large frame, and carry a staple of at least 3in. to 3½in. The wool should be clean, sound, and of a 64's quality. The Merino should have clean points, clean face with a good crop of wool extending down the centre of the head a little past the eyes, but not interfering with them. This breed generally proves the most profitable for all-round farm use. Lincoln is one of the largest sheep, has the heaviest and longest wool, and consequently it carries the heaviest fleece. Romney Marsh is the most suitable for very wet marshy or swampy countries. For the districts south of Adelaide a very profitable line is the longwool crossed with the Merino. Two good strains for this are the Border or English Leicester. A cross of this kind reduces the fleece value by approximately 2s. 6d., but this can readily be made up by extra weight in fat lambs.

*Feed.*—The correct feeding of sheep is a very important matter if maximum returns are desired. For best results sheep should have a nourishing and comparatively even amount of feed all the year. The quantity and quality of the feed affects the staple of the wool considerably. If sheep are taken from good pastures and starved for a couple of days and then put back again, it may cause them to lose their wool entirely, or at least make it very unsound. In some months during the year feed is more plentiful than at others. To overcome this defect, I should like to suggest an item that has received very little consideration by many farmers in this district, that is top-dressing. *Top-dressing.*—Why should not super have the same beneficial effect on fodder crops as it has on cereal crops in normal years. For top-dressing, I should suggest pasture land that has an established growth of foddere and herbage, under reasonable circumstances, and a rainfall of, say, 11ins. or over. It has many points in its favor. A few are:—The quantity and quality is increased; a number of natural grasses little seen in normal years soon make their appearance, do well, and spread over the pasture; whilst other kinds, like silvergrass, which is generally disregarded by the stock, is then readily eaten. More lime-phosphate is supplied to the stock by fertilised plants, and a greater amount of portein is available from the increased growth of legumes, such as lucerne, clover, &c. From personal experiments carried out in the form of grazing plots, dressed with 50, 100, 150, 200, and 400lbs. per acre; each of these plots has received an annual dressing the last four years, results have been remarkable. Another two plots were laid out five years ago, and neither have been grazed. One plot is no manure, whilst the other received an annual dressing equivalent to 2,985lbs. of 45 per cent. super per acre. The result has been a real surprise. It is now producing more than tenfold the fodder, and of a superior quality to that of the untreated plot. I do not wish to maintain that a heavy dressing of this kind is very profitable, nevertheless it shows the influence super has on foddere. If top-dressing is handled right it should help to solve some of our feed problems.

*Shearing.*—See that only careful persons are employed; rough handling, etc., not only affects the value, if sold immediately after shearing, it also causes pain to the sheep, and there is a danger of germs entering through the wounds of the sheep.

*Skirting.*—This should be done as lightly as possible, only removing the tips of the legs, neck, breech, sweaty edges, or any other part the operator deems necessary.

*Classing.*—Make all lines as even as possible, by casting out all the inferior fleeces, such as extra heavy, discolored, kempy, matted, very short, very tender, and extra strong. These lines reduce the sale value of the good fleeces. With small flocks it is often more profitable to let the broker do the reclassing, but before sending away be sure all bales are branded correctly, both top and front.

*Culling* is generally easiest accomplished if the breeder can watch the sheep on the shearing-board and mark all those producing poor or inferior fleeces or possessing any other fault; these he can then fatten and

dispose of. *Mating*.—By careful culling and always attempting to use the one strain of rams, the breeder should soon obtain a very uniform flock. Rams should not be kept too long, because after five or six years they have a tendency to get slow, and also lack fertility, and this means a low percentage of lambs. Some breeders make it a practice to include a few young rams towards the end of the season. This 'liven's up' the old ones, and the young ones have a small season to start with.' (Secretary, Mr. F. Wurst.)

#### BLACK ROCK (Average annual rainfall, 12.57in.).

August 26th.—Present: 12 members.

*CARE OF MACHINERY*.—In reading a paper on this subject, Mr. J. Hurst said the low price of farm produce and the high cost of all farm implements made it very necessary that every care should be exercised with all farm machinery. The first essential was to see that all nuts and bolts were kept tight, and to see that all moving parts were well oiled and greased. Good shelter for all implements containing any woodwork should be provided. After harvest all worn out or broken parts should be replaced. If left until next season there was the danger of their replacement being overlooked when operations commenced for the next season. With so much machinery to keep in good repair, a well equipped blacksmith would prove of very material assistance. He suggested the use of a link for the centre of swings rather than an eyebolt, the latter had a tendency to weaken the swing. An occasional coat of paint to the woodwork would be a good investment, it would considerably lengthen the life of the implement or vehicle. The wheels should be kept in good order, especially the tyres. Wire, whilst an excellent friend in time of need, was too frequently made to serve the purpose of a permanent repair. Small tools, such as bars, picks, shovels, &c., should be returned to their place in the shed after use. (Secretary, Mr. R. Kitto.)

#### EURELIA (Average annual rainfall, 13.14in.).

Meeting held September 3rd. Mr. C. Stott presided over an attendance of 10 members and visitors. Members discussed the papers which were read at the Upper Northern Conference. (Secretary, Mr. E. Wall.)

#### EURELIA WOMEN'S (Average annual rainfall, 13.14in.).

Twelve members attended the meeting held on October 1st, when an excellent report of the Adelaide Congress was tendered by the delegates who represented the Branch. (Secretary, Mrs. E. Wall.)

#### WABCOWIE (Average annual rainfall, 12.16in.).

September 2nd.—Present: 11 members and four visitors.

*FENCING*.—The meeting was held at the residence of Mr. H. Jarvis. Mr. W. Crossman read the following paper:—"A good boundary fence should be made with wire netting, the posts being 5ft. 6in. long and 20in. in the ground, and spaced 5yds. apart. The strainers should be 7ft. long, and 30in. in the ground, and about five chains apart. This, with a 3ft. 6in. netting, 4in. in the ground, and a barbed wire 8in. above, would make a fence 3ft. 10in. high. A good sheep-proof fence of six wires could be made of posts 5ft. 2in. long, 20in. in the ground; strainers 6ft. 8in. long, 30in. in the ground; the wires being as follows:—First, 6in. above the ground; second, 6in. above first; third, 6in. above second; fourth, 6in. above third; fifth, 8in. above fourth; and sixth, 10in. above fifth wire. This would make a height of 3ft. 6in. For a five-wire sheep-proof

**FREDK. COLEMAN,**

**TUELA, SADDLEWORTH.**

fence posts should be 5ft. long and strainers 6ft. 6in. long, and in the ground 20in. and 30in. respectively; the wire spaces being 6½in., 6½in., 7in., 9in., and 11in., the height being 3ft. 4in. For a dog-proof fence it was not advisable to erect one under 6ft. high. This should have a 3ft. 6in. netting on the bottom and 3ft. on the top, the bottom being 6in. in the ground. It was a good plan to leave the posts 6in. to a foot higher in case one needed to put a barb or two on top to make it higher." A good discussion followed, and Mr. G. Hilder thought 1ft. netting lying on the outside of the fence was a splendid thing for keeping dogs from getting in. (Secretary, Mr. W. Crossman.)

## MIDDLE-NORTH DISTRICT.

### (PETERBOROUGH TO FARRELL'S FLAT.)

BLYTH (Average annual rainfall, 16.94in.)

There was a large attendance of members and visitors on the occasion of the annual meeting which was held on August 26th, when addresses were delivered by Messrs. W. J. Spafford and W. C. Johnston of the Department of Agriculture. (Secretary, Mr. L. Mugge.)

GLADSTONE WOMEN'S (Average annual rainfall, 16.44in.).

The meeting of September 5th was held at the residence of Mrs. Spotswood. Musical and elocutionary items were rendered by Mrs. Pritchard and Mrs. Randle. (Secretary, Miss M. J. Sargent.)

GLADSTONE WOMEN'S (Average annual rainfall, 16.44in.).

December 12th.—Present: 20 members and two visitors.

CAKE COMPETITION.—In the cake competition for the trophy to be presented at the next annual meeting, the judges—Mesdames Destree and Sandow—made the following award of points:—Mrs. Gravestock, 50; Miss Sargent, 49; Mrs. Smallacombe, 48; Mrs. Hackworth, 47; Mrs. W. Thomas, 46; Mrs. C. Lines, 45½; Mrs. R. Lines, 45; Miss Porter, 45; Miss Brown, 44. (Secretary, Miss M. J. Sargent.)

### KOONUNGA.

Meeting held August 5th. Present: 22 members. Addresses were delivered by Messrs. W. Brownrigg and W. Johnston of the Department of Agriculture. (Secretary, Mr. G. Cartwright.)

KOOLUNGA (Average annual rainfall, 15.61in.).

Meeting held September 2nd. Present: Mr. H. Spencer (Chair) and 14 members. The Secretary, Mr. E. Le Page, read a lengthy paper, "Grain for Market and Marketing." A keen and interesting discussion followed.

### NELSHABY WOMEN'S.

Meeting held September 4th. Present: 12 members.

ART NEEDLE WORK.—Miss E. Haines read the following paper:—"Art needle work in a home is one of many things which help to beautify it. There are many different kinds of work classed as 'art needle work,' but I propose to discuss mainly work involving the use of needles, and will endeavor to give a few points on stitchery and coloring. *Material, Threads and Coloring.*—Coloring can make or mar the work. Use good material, as it is a waste of time putting good work on to common material—Semeo traced goods are reliable. Colored work is very nice, and at the present time is popular and fashionable, but in a few years' time it may be out of fashion. For work that is to last, nothing is better than 'white' work. White linen worked with white thread looks rich and good, and is never out of fashion. 'D.M.C. Cotton A' Broder, red label,' is very good for white work. For fine white work 'D.M.C. Perle Cotton, No. 12,' works up wonderfully well, and has a silky appearance when finished. 'D.M.C. Stranded Cotton' is the best colored cotton. It has a soft touch, and when worked has a silky appearance. Stranded cotton is the cheapest, because for fine work one need only use a single strand. For flowers and leaves two strands are best, with one strand for stems. If using more than two for flowers, use two for stems. In making tray cloths, d'oyleys, toilet sets, &c., either a white or colored linen or Indian head may be used. If a colored material, see that colors used blend with it. If colors do not harmonise, all one's work is wasted. For instance, never work a purple flower alongside a red or blue flower. These colors may be used, of course, but see that they have a yellow or autumn tint between them. Also, be careful what shade of

green is used for stems close to a blue flower. Use light green with pale flowers and dark green with dark flowers. When using pale shades, see that all are pale, and *vice versa*. Be careful when purchasing silk threads. A stiff silk is not much good. 'Classic' and 'Mallard Floss' are two good silks. If using 'Classic' on a soft material, such as crepe de chene or georgette, always press the thread before using. For underclothing use a soft, stranded silk. *Working*.—Never tie a knot in the thread, but catch thread to linen at back very neatly. When finishing off run the needle through some of the stitches at the back, pull firm, and cut the thread. When the cloth is finished it should be just as neat at the back as at the front. If keeping work it is advisable to wash and boil. Do not blue or starch it. The starch will rot the linen. Never get the work heavy-looking or 'plastered.' A cloth will look more effective if worked simply. *Stitches*.—'Open work' looks well on white linen. There are three different kinds of open work—Richelieu, Roman cut, and Venetian work. Richelieu is the design cut out—commonly known as 'ladders.' Roman is a design cut out and connected with bars. Venetian is the design cut out but without bars. Some very simple stitches can be introduced into the work, amongst them being lazy daisy, thousand flower, stem stitch, French knots, twisting, chain stitch, Indian filling, and bullion stitch. Lazy daisy can be used for flowers and leaves, thousand flower for flowers and leaves, stem stitch for stems and any outlining, French knots for centres of flowers, twisting and chain stitch for outlining, Indian filling for centres of flowers and filling in, and bullion stitch for flowers. Although lazy daisy is one of the easiest of stitches, it is very often worked wrongly. First, catch the cotton to the back of work, bring needle through at point of petal nearest centre of flower, put needle back in same hole, bring point of needle out at end of petal with thread under needle, pull needle through, pull thread tightly. Always leave a long point at the end of the petal, and work towards the left. (2) Thousand flower is just a straight stitch; catch cotton at back, bring needle through at centre and down at the point of petal, always working towards the right. (3) Stem stitch; catch cotton at back, bring needle through at the point nearest to one's hand and work outwards, take up small bit of material, pull tightly. (4) French knots; catch cotton at back, bring needle through to right side, twist cotton two or more times around needle, put needle back into same hole, pull through and finish off. (5) Twisting; catch cotton with one color, do a running stitch, and with another color twist in and out of running stitch. (6) Chain stitch; catch cotton at back, bring needle through to right side, put needle back into same hole, bring needle through, say at about one-eighth of an inch, thread under point of needle, and pull through, working towards you. For the heavier colored works, such as cushions, curtains, covers, supper cloths, tray cloths, &c., we have more of a variety of stitches to choose from amongst them being satin stitch, double cable, solid Kensington, eyelets, and crewel stitch. For underclothing or babies clothes, herringbone, Craig, feather stitch, feather and rose, snail trail, and oyster stitch are effective variations. Roses can be either fibron or bullion stitch, both look very pretty. Hand hemstitching also makes an effective trimming, and is quite easily done. *Wool Work*.—Rainbow brand wool is the best for any embroidery work. For knitting use Scotch fingering or Baldwins & Patons' wool, two-ply baby wool being the best for babies' clothes. Any wool is suitable for tapestry work. *Knitting*.—First master the 'plain' stitch, then the 'purl,' after which it will be possible to learn fancy stitches. See that the needles used knit the wool easily. If the needles are coarse, a coarse wool is required, or the knitting will be too loose. Size 8 needle is suitable for four-ply wool. For coarse knitting use size 7, while for two-ply wool use size 10. Always cast on firmly, counting the cast on stitches as a 'knit' row. Develop an 'easy' style of knitting. If the stitch is either too tight or too loose, the finished article will not be smooth and even. Finish off the work firmly. One of the easiest articles to knit is a scarf. Babies' clothes and underclothing are also comparatively easy to make. Dresses and jumpers are more difficult, because the work must be shaped as it progresses. When buying wool it is advisable to purchase a little more than is required, because one may not be able to match it, and the knitting will then be wasted. For babies' clothes, pale, delicate shades must be used, but for grown ups bright, gay colors can look very smart. Never use cheap wool, particularly for socks. *Crocheting and Tatting*.—Some years back crocheting and tatting were quite out of date. Now they are very fashionable. Both make effective edges when worked around tray and supper cloths, d'oyleys, handkerchiefs, etc., and on underclothing. Dresses, shawls, babies' wear, slippers, bed socks, and many other articles may be crocheted. However, crocheting is much more expensive than knitting, because it uses more silk or wool. *Tapestry Work* is another expensive work; it requires a considerable quantity of wool, but the work is well warranted. Beautiful designs may be obtained for fire screens, cushions, stools, and furniture. Making floor rugs is another fascinating work, and even though they take a lot of wool are much cheaper than those purchased. *Stencilling*

is a very easy way of painting articles, and can be used on dresses, curtains, cushions, etc. The work can be much improved if some of it is outlined in silver or gold.

**Cushions.**—These can be useful as well as ornamental. A useful cushion can be made from a sugar bag. Get a clean sugar bag and unpick sewing, then dip in a dye made from 1 tablespoonful of Condyl's crystals dissolved in 2galls. water. Hang on the line while dripping wet. Whilst still damp, press with hot iron. Make into whatever size cushion required, fray bag at each end to form a fringe, and work design on side with either wool or raffia, using any stitch such as buttonhole, chain, single cable, running stitch, and twisting. Such cushions can be used in the car, kitchen, or in the garden. Arris cloth and poplin also make serviceable cushions, either worked or painted, and can be used for comfort in the house. Satin and silk poplin worked in silks, painted or plusette, and rucked or corded, can be made into elaborate cushions. Such cushions are made to be seen and not used. Curtains look beautiful if worked in silk or plusette.

**Bead Work.**—Beaded designs on cushions look extremely smart. Evening bags in beaded designs are expensive to buy, but if one gets a fine canvas, a bead needle, and No. 8 perle cotton, together with various shades of beads, hours of stitching will result in a beautiful evening bag. *Raffia Work* is at present very popular. Designs may be worked on bags, cushions, trays, baskets, and boxes. To make a bunch of cherries from raffia, get a large bead, thread a large needle with red raffia, cover bead all around. For leaves, draw a leaf on stiff canvas, work with buttonhole stitch, then cut out, hang each cherry on a piece of green raffia and form into a bunch. This can be put on the top or side of a box, or in one corner of a cushion. Any flowers can be made in practically the same way." (Secretary, Miss A. Lawrie.)

#### NELSHABY WOMEN'S.

Mrs. Jose presided over an attendance of 12 members at the meeting held on October 2nd, when a report of the Annual Congress was supplied by Mrs. F. Jose and Miss A. G. Lawrie (Secretary).

#### WANDEARAH.

August 12th.—Present: 18 members.

**SHEEP AND WOOL.**—Mr. N. Dennis delivered the following address:—"As most farmers keep a few sheep in conjunction with their farming pursuits, it should be their aim to get as much profit out of them as possible, as well as keeping the fallows clean. For this purpose I advise keeping a good class of Merino ewe with a good, large frame, and strong wool, say of a 60's type, and if purchasing ewes for breeding, always buy ewes from four-tooth to six-tooth and mate them with a crossbred ram. My first choice for this purpose is a Dorset Horn, and secondly, one of the Down breeds. These rams get an early maturing lamb which should be ready for market at about 16-20 weeks of age. I advise mature ewes for this purpose, because the crossbred ram has a tendency to leave a lamb rather coarse in the head and shoulders, so that with young or maiden ewes there is a risk with both ewe and lamb. Mate the ewes about the end of November with one ram to not more than 40 ewes. I advise yarding the ewes during the main lambing period, because foxes are so troublesome that a large number of lambs dropped are taken in the night. Farmers should endeavor not to overstock, try and keep the sheep in good condition all the year round, then one can often catch a good market with dry ewes and replace them with sheep in store condition, and so make a few pounds of ready cash. Shear in the latter part of August or early September to give the sheep a chance to get into good condition on the flush of feed and so have them strong to be able to withstand the dry periods. Sheep that are fat will go through the summer on scant rations if they have plenty of water and a little shade provided for them. It does not pay the small flock owner to class the wool into too many lots. Make one lot of the best fleeces, not skirting too heavy, but see that most of the dirty edges are removed; take the bellies and best pieces and brand as such in one lot, the sweepings from the board and stained pieces should be branded as locks, making in all three lots. Keep the ewes well crutched, this will be a check on the blowfly, as they seem to require a certain amount of moisture to work on. Efficient dipping also helps to minimise the blowfly menace. When breeding for lambs the farmer should try to get rid of all crossbred lambs, either by sale or slaughter for rations; they are bad on fences and tend to make rogues of otherwise quiet sheep. The fact of having a few crossbreds at shearing time also causes extra work with the grading of the clip. Always try to have only a straight line at shearing time. For the man who keeps just a few sheep for ration purposes, I have found it quite satisfactory to have a ram with the flock at all times, so as to have a supply of smaller mutton on hand."

Mr. C. Perry delivered the following address, "The Type of Sheep for the Farm":—"The type of sheep for the farmer must chiefly depend on the locality where they are

depastured. For instance, in the drier districts, where the rainfall does not exceed an average of 10in., it is a mistake to try and keep any breed except the Merino. Experience has proved that the Merino is essentially adapted to this class of country, as it can withstand the hardships common to all these areas. The Merino can live on comparatively little food; the British breeds, on the other hand, require more food and water. After the locality has been decided, what branch of the industry does the farmer wish to pursue is the next question? Does he mean to keep sheep merely for the purpose of keeping his land clean, if he be an agriculturist, or for shearing them? Or does he intend to raise fat lambs for the market, breed sheep and sell fat wethers, or breed sheep and sell his increase as stores to the man who buys for fattening? Referring to the farmer who keeps sheep chiefly to keep his land clean and incidentally to get what profits accrue from depasturing them, the chances are that such a man will buy sheep rather than breed them. In such a case it is advisable to buy from a good flock. By buying sheep simply because they cost little, the chances are that the farmer will never be able to fatten them, and when he has to sell he will probably get little or no profit on his purchase. If he wishes to breed, there is no question about the advisability of having good stock to commence with. *Fat Lambs for Market.*—The first point is to know whether the locality is suitable. The practical man will know that in order to successfully breed fat lambs for market the country must be suitable, and what is also very important, there must be a ready access to a market, because the longer time the lambs are on their way to market the more they deteriorate in value. *Breed of Sheep.*—Here, again, the locality plays an important part, and it is fairly safe to say that where the rainfall is not more than about 20in. it would be found advisable to use a big-framed Merino ewe and one of the early maturing breeds of rams. The Shropshire, Southdowns, and Dorset Horn are all excellent rams for this purpose. In wetter localities, where the rainfall is 25in. or over, it may be advisable to keep half-bred ewes, and in this respect the half-bred Lincoln or Leicester ewe, or in exceptionally wet localities the half-bred Romney Marsh will be found very useful. Under wet conditions they are good doers and proved excellent mothers. The ram used in this instance should be a choice from the early maturing breeds already mentioned. *Raising Fat Wethers.*—This has been found to be profitable in certain districts, but it is only under special conditions that one can recommend such a course. If the land is good, and the farmer adopts this branch of the business, it is essential to have the big-framed sheep. If it is on a Merino country, then the big-framed type of Merino by all means; if, on the other hand, it is crossbred country then the Crossbred Leicester, Lincoln, or, under wet conditions, the Romney Marsh. In advocating the Leicester, Lincoln, or Romney Marsh crossbreds one is influenced by the fact that not only do these sheep produce a big weight of wool, but it is always saleable, whereas the other English types which, although much earlier maturing, do not produce either the same weight or quality of fleece. Finally, as to whether it is advisable to sell rather than fatten, the class of country must be the guide. Here, again, it is advisable to use the bigger framed Merino in Merino country.' (Secretary, Mr. J. O'Shaughnessy.)

## LOWER-NORTH DISTRICT.

### (ADELAIDE TO FARRELL'S FLAT.)

AUBURN WOMEN'S (Average annual rainfall, 24.12in.).

September 26th.—Present: 11 members.

The meeting was held at Miss Dennison's residence. The report of the delegates to the Annual Congress was discussed.

**CAKE FILLINGS AND DECORATIONS.**—Mrs. Wishart read the following paper at the meeting held on October 31st, which was attended by 13 members:—"In cake filling there are a variety of makes and flavors to choose from, and when used with layer cakes most suitable for fillings they are very acceptable at afternoon teas and suppers. Cakes mostly used, and to which a nice filling both improves the taste and appearance, are plain sponge, butter sponge, ribbon cake, cinnamon sponge, and ginger sponge. Care must be taken to have cakes cool before commencing the fillings or decorations. Should there be a number of cakes needing fillings, make sure all the required ingredients are on hand before beginning. Icing sugar should be crushed and put through a sieve before using to get best results. When using a flavoring in a cake use the same in the filling. When using whipped cream as a filling, the cake must be used while the cream is still sweet. A plain sponge is most suited for a vanilla flavored whipped cream. Butter sponges need a filling flavored with the juice of a lemon or orange. A butter filling can be used to advantage in ribbon cake, layer cake, and ginger sponge. In decorating a cake, say for a birthday, trim off the top to make the cake level,

then turn underside upwards, to give a nice smooth surface on which to work, and place the cake on a flat plate. Icing should be made with the beaten white of an egg to a stiff froth, adding enough icing sugar to make a stiff paste. Cover the cake with one layer and allow this to set. Give another covering, adding the decorations at the same time. Cakes can also be made to look attractive at little expense by using colored icing in contrast with white icing. *Lemon Tart*.—Ingredients: 1 cup S.R. flour, 1 egg, 1 tablespoon butter, a little sugar, pinch of salt, and mix with milk. Filling: 1 tablespoon cornflour, 1 cup of sugar, yolk of an egg, grated rind of 1 lemon and the juice, 1 cup of water. Method: Put into a saucepan and boil, stirring all the time. Fill tart with mixture. Beat white of an egg to stiff froth, add a little sugar, and spread on top of cake. If preferred, date filling can be used— $\frac{1}{2}$  lb. dates, 1 apple, 1 teaspoon ground ginger, and stew ingredients in a little water. *Apple Cake*.—Ingredients:  $\frac{1}{2}$  lb. butter,  $\frac{1}{2}$  lb. sugar, 4 eggs, 1 cup milk,  $1\frac{1}{2}$  lbs. S.R. flour. Method: Melt butter and sugar together, beat well, add egg one at a time, then add milk, and lastly flour. For the top of the cake  $\frac{1}{2}$  lb. plain flour, 2 ozs. sugar, and 1 teaspoon cinnamon are required. Mix these together, and peel, core, and slice 6 apples. Melt  $\frac{1}{2}$  lb. butter and mix dry ingredients with melted butter until lumpy. Spread a little melted butter over the cake mixture, then apples, then the dry mixture, and bake." (Secretary, Miss L. Dennison.)

#### AUBURN WOMEN'S (Average annual rainfall, 24.12in.).

November 27th.—Present: 10 members and two visitors.

**JAM MAKING.**—Mrs. J. Schmerl read the following paper:—"Select fruit that is firm and sound, fruit that is over-ripe will not set nicely and is more likely to candy, ferment, or develop mould, because there is too much sugar and not enough jelly in it. For boiling jam I prefer a shallow enamelled pan, because it allows free evaporation. On no account have a lid on the utensil in which the jam is to be boiled. Insufficient cooking is often the cause of failures. The jam will not set, and over cooked jam loses not only the color, but destroys the jelly that every fruit contains. Sugar acts as a preservative, and brewers' crystals are generally better to use. I have used it for one whole season's jam making, but cannot say that I have found the difference very noticeable. Manufacturers claim that one needs less sugar by using brewers' crystals than the fine sugar, but I think the difference is about equal, because crystal sugar is always several shillings dearer than the A1 fine. My experience has shown that by adding in most cases 1 lb. of sugar to 1 lb. of fruit one will achieve the most success. I select firm fruit, cut it up (cut plums in halves), put into pan with about 1 lb. sugar and just a little water, and boil until tender. Apricots take only a little while, plums, &c., longer. Then add the sugar and boil quickly for about half to three-quarters of an hour. Always boil jam quickly. *Sweet Marmalade*.—4 lbs. oranges, 5 lemons, 12 lbs. sugar, 16 cups water. Cut oranges and lemons and stand over night in the water, boil fast for half an hour, then put in sugar and boil until it jellies (about one hour); it is generally then quite thin, but will jelly after about three days. *Gooseberry Jam*.—To every pound of gooseberries add 1 pint of water, and boil until tender. Add  $\frac{1}{2}$  lbs. sugar and boil about half an hour, or until the fruit turns to a pretty pink color." (Secretary, Miss L. Dennison.)

#### BLACK SPRINGS.

August 5th.

Meeting held August 5th. Present: 12 members. The meeting took the form of a Question Box, when several subjects of local and timely interest were introduced, and an interesting discussion ensued. (Secretary, Mr. K. Dunn.)

#### BLACK SPRINGS.

September 2nd.—Present: 11 members.

**COST OF WHEAT PRODUCTION.**—Mr. A. Mickel read the following paper:—"During the years that have passed since the production of wheat has become general, much has been done to obtain maximum yields. Agriculture has reached a stage when one is at a loss to know in what direction to turn to increase production. There is one factor, however, that is the controlling influence in success, and that is rainfall. All avenues of cultivation and most productive varieties of wheat and scientific methods have not, and never will, overcome the vagaries of the seasons. Without rain in sufficient quantity and at the right time of the year, the farmer's efforts are futile, as has been the case in many parts of the State the last few years. Not only has the farmer's labor been in vain, but seed, super, fodder, or oil and tractor fuel have been wasted, and his efforts have failed. The farmer has so much at stake that he has no option but to stick to it whether good seasons or bad ones prevail. Decreased cost of production is the only avenue of relief that presents itself to the farmer at the present time, and

this is ruled by many governing factors, primarily by the fact that the farmer is not able to pass on to someone else the cost of production, and has to take what is given to him for his produce; but there is room for improvement in his conditions, and to bring about such there should be created a governing body to protect his interests. The manufacturers have their Chamber of Manufactures, and the commercial men have their Chamber of Commerce, but the farmer has no means of redress for his grievances."

On August 4th an inter-Branch visit was paid to the Hanson Branch, and the subject, "Is land too expensive in this District" was debated. The speakers from the Black Springs Branch were judged the winners of the debate. (Secretary, Mr. K. Dunn.)

#### BRINKWORTH (Average annual rainfall, 16.01in.).

Mr. E. Carlyon occupied the chair at the meeting held on August 4th, which was attended by 23 members and several visitors. Addresses were delivered by Messrs. W. Brownrigg and W. C. Johnston, of the Department of Agriculture. Mr. H. Ottens read a paper, "The Cost of Producing Wheat." (Secretary, Mr. H. Ottens.)

#### BROWNLOW.

August 6th.—Present: 18 members and four visitors.

**SHEEP ON THE FARM.**—Mr. F. Roocke presented the following paper:—"In selecting a flock of sheep for the farm it is essential that one choose the type of sheep most suitable to the district. For this district, the large-framed fairly plain-bodied Merino is best; they do better than other sheep in very dry seasons. See that the sheep are not too loose and open in the wool, otherwise sand and dust will then enter the wool too easily. Breeding ewes should not be too woolly about the face, or the offspring will generally be wool-blind, unless they receive close attention. A sheep that can see where it is going is bound to do best, especially when feed is scarce. The wool should be as even as possible throughout the flock. To arrive at that it is necessary to cull every year, keeping the ewes with a good even-quality wool, good constitution, and large frame. If possible, dispose of all the old, poor woolled, small, and unthrifty ones. By keeping young sheep one gets a better return per sheep than by keeping old ones. It is most profitable to sell all wether lambs and ewe lambs which are not wanted for breeding when they are five or six months old. Even when in only fair condition they usually bring a good price. A lamb at that age will fetch as good a price as a full-grown sheep. Sheep are very useful on the farm for keeping down weeds on the fallow, and for cleaning up the last of the stubble after the larger stock have finished with it. A few sheep should be kept on every farm, if only to supply the household with meat. Sheep must be watched closely to see if any are flyblown. 'Prevention is better than cure,' so it is better to crutch the sheep fairly often than to be continually treating flyblown sheep. They should be kept in a healthy condition; poor sheep are generally the first ones struck by the fly. All ram lambs should be docked as young as practicable, preferably when two or three weeks old, as they recover much quicker than when they are older. To perform this operation one should have a knife with the back part of the blade blunt. The end of the purse should be cut right off and the testicles taken between the thumb and the blunt part of the blade and drawn out gently. An antiseptic should be applied, to prevent germs getting into the wound and sometimes causing lockjaw. The tail should be cut fairly short, especially that of ewe lambs. Care should be taken not to drive sheep too far immediately after lambs have been tailed. In summer see that the sheep have plenty of water. They will do fairly well even if

there is not very much feed about, providing they have plenty of good water and not too far to go to it. Any bad fencers should be disposed of as soon as possible, because they will soon get the flock into the bad habit of getting through fences. Wool is damaged and lost in this way. When there is plenty of dry grass left in the summer it is best to mate ewes in December and January, or perhaps a little earlier, to have the lambs dropped before the cold weather sets in. Rams should never be left with the ewes all the year; this causes an irregular drop of the lambs, and there will never be as good a percentage of lambs as when they are only joined for a short time, say two months. If only one ram is kept, it should be put with some wethers in a separate paddock or kept in a small enclosure and hand-fed. If the ram runs with the flock all the time he should wear an apron, although keeping the ram away from the ewes except at the mating time is best. Lambs should never go through the summer with the wool on their backs. The fleece at the second shearing is better when they are shorn as lambs, and they do not gather so many grass seeds. Shearing before summer will ensure better conditions, and will lessen blowfly trouble. Young ewes should never be mated to any of the mutton breed rams or there will be a great loss at lambing unless assistance is given to the ewe. Now that wool is low in price it would be quite a payable proposition to breed crossbred lambs, providing the farmer has plenty of feed. They mature earlier than the Merino and fetch a better price on that account." In answer to questions, Mr. R. Smith, a member of a neighboring Branch, recommended the tailing of lambs before they were six weeks old. For owners of 100 or smaller lots it paid to have wool classed in the city, providing the dusty back was first removed. He also recommended keeping all ewe lambs for improving the flock, and agreed with Mr. Rooke that the Merino was the best sheep for the district, as they were more active than other sheep. (Secretary, Mr. T. Partridge.)

#### BROWNLOW.

September 3rd.—Present: 16 members and three visitors.

The meeting took the form of a "Question Box," the following subjects were discussed:—What is the best way to prevent soil from drifting? *Answer*—Leave belts of timber across the path of the prevailing wind, work soil when wet, and leave unharrowed. What is the best remedy for a horse that injures its shoulder? *Answer*—Apply Schmidt's liniment and bathe with warm water alternately, using one to-day and the other to-morrow. What is the best way to remove rivets without injuring the leather? *Answer*—Place the rivet over a hole in iron and knock out with a punch. Does lucerne need much water? *Answer*—Yes. Cut often and water freely.

CLARE (Average annual rainfall, 24.67in.).

August 5th.—Present: 18 members.

MANURING FRUIT TREES AND VINES.—Mr. A. Ninnes (Secretary) gave the following address:—"Method in which Plants in general obtain their Food.—There are two main sources, namely, the air and the soil. The plant absorbs carbon dioxide or carbonic acid gas from the air through its leaves and gives out oxygen, while from the soil it takes in its water supply with small quantities of dissolved mineral salts. The supply of carbon dioxide is out of our control, and so is the water supply to a large extent in this district. We can only cause a greater amount to be available to the plant by more efficient cultivation. It is to the mineral salts that we must now turn our attention. Elements necessary to build up a plant are carbon, hydrogen, oxygen, nitrogen, sulphur, phosphorus, potassium, magnesium, calcium, iron, and silicon and sodium to a lesser extent. Of these only carbon comes from the air, while the others are absorbed as salts dissolved in water. These salts in the soil must be rendered soluble in water if insoluble, as it is of no use applying manures which do not contain the plant food in a soluble form. However, the insoluble plant foods may be made soluble by the application of substances classed as soil amendments, such as gypsum and lime. These substances are very often applied to make the potash in the soil soluble. In dealing with the question of manuring, we turn mainly to the three elements—nitrogen, phosphorus, and potassium. So far as wheat-growing is concerned, the phosphate compounds are usually the most deficient. Nitrogenous compounds are also lacking, but by careful cultivation, bacteria in the soil are able to collect enough nitrogen from the air to supply the wants of the cereal crops. Except in the case of poor, sandy soil, we find enough potash compounds, although in some cases they are in an unavailable form. *Nitrogenous Phosphatic and Potassic Fertilisers*.—Each have a specific action on all plants. Nitrogen promotes vigor, gives largely to development of shoots and leaves with a dark, green color. Thus, weakened vines should receive large dressings of nitrogen, whilst very vigorous vines and unproductive ones require little or no nitrogen. An excess or too much nitrogen gives grapes rich in nitrogenous compounds, fairly soft and susceptible to

disease, and of low-keeping qualities. Wine from these grapes take a long time to become bright and is especially subject to bacterial diseases. Vines are more subject to all kinds of bacterial diseases, and grapes cannot ripen owing to the shortage of water in the soil, which is caused by excessive transpiration of soil moisture through the large amount of foliage. The wood is also retarded in ripening. However, organic nitrogen, as applied in green manuring or farm yard manure, increases the water-holding capacity by the addition of that all-important substance, humus, and therefore is not so injurious as excess mineral nitrogen. The addition of phosphates to a large extent neutralises the evil effects of excess nitrogen. With the phosphates, production increases and the berries set much better; it also gives a better ripening of the grapes and wood, which takes place sooner and more completely. The phosphatic content of the grape is increased, which greatly favors fermentation in wine, and also its quality, thus accounting for the heavy dressings of phosphates in the French districts that produce the high quality wines. Root development is considerably increased, this being particularly valuable in clay and ripening is hastened. If grapes are harvested early or complete ripeness is not reached, crops that have received dressings of phosphates will be richest in sugar, because phosphates hasten ripening. Thus, the sugar content of the grapes is raised in cold districts, not directly but indirectly through earlier and therefore better ripening. Lack of potash is evident from the poor, dull color of leaves and loss of rigidity in shoots. Such plants are much less resistant to diseases and pests, than plants with normal potash requirements. It helps to neutralise the acid in the juice of grapes and so prevents the must being too acid; it usually contains more free acid in a dry summer. Potash plays a very important part in the formation, translocation, and deposition of sugars and starches which are found chiefly in the fruits. Thus potash is a very important factor in the production of the fruit of both vines and fruit trees. *The Materials Removed by the Vine.*—Mr. F. de Castella gives the following figures for an average crop of 5 tons of grapes per acre:—Nitrogen, 33lbs.; phosphorus, 9lbs.; potash, 27lbs. The famous German research worker, Wagner, found that there were only very slight variations with different varieties of grapes, and Muntz gives the following figures for the amount of each element absorbed by the different parts:—

| Parts of Vine.   | Nitro.<br>Per cent. | Phos.<br>Per cent. | Pot.<br>Per cent. |
|------------------|---------------------|--------------------|-------------------|
| Leaves . . . . . | 66                  | 50                 | 50                |
| Canes . . . . .  | 16                  | 20                 | 25                |
| Grapes . . . . . | 25                  | 33                 | 33                |
| Wine . . . . .   | 3.4                 | 10.4               | 13.9              |

From the above figures it will be seen that wine only removes a small portion of the mineral food taken up by the vine, therefore, if the canes and leaves in the vineyard are kept, and the marc (seeds and skins) is returned, there is very little plant food to be supplied. Under practical conditions only about one-third of the leaves is returned to the soil, and usually only the ashes from the canes, which, although very important, is not the complete mineral content because the nitrogen is lost in burning, and in a goodly number of instances growers do not return the seeds and skins or their equivalents. To make up this shortage, we must supply the soil with fertilisers in some form or other, although it may not seem necessary, because the vine reaches to a much greater depth than the average cereal crop, but it is found that after a number of years, except where very rich soils exist, the vines have a tendency to reduce their crops. This is due mainly to the fact that the food supply is becoming deficient. Perold, in discussing this question, recommends that the composition and nature of the soil, as well as the climate, should be taken into consideration. Thus it is difficult to give a strict formula. He recommends that the following amounts should be applied to a vine in some form or other:—30-40lbs. nitrogen, 40-60lbs. phosphorus, 40-50lbs. potash. These quantities are found in:—150-200lbs. ammonia sulphate, 160-240lbs. superphosphate, 112lbs. sulphate of potash. However, it would not be recommended to apply the above quantities of expensive fertilisers, but we must consider the ways in which the equivalents may be applied. As we have no experimental data, I quote the manurial dressings applied in this district:—1½cwt. ammonia sulphate, 2½cwt. superphosphate. Another is:—1cwt. ammonia sulphate, 2cwt. superphosphate, 1cwt. sulphate of potash. *Method of Applying the Food Material.*—All three can best be applied in the form of a well-rotted farmyard manure. In 4½ tons per acre we would thus be giving 36-54lbs. nitrogen, 18-27lbs. phosphorus, and 45-63lbs. potash. This quantity would be sufficient except as regards phosphates. Farmyard manure also supplies organic or vegetable matter which turns into humus. Humus increases the water-holding capacity as well as the physical condition, by making it more pliable. In most gardens there is not sufficient stable

manure each year to do the whole vinyard. If there is enough to fertilise, say a quarter annually at the rate of 4½ tons per acre, divide the vinyard or orchard into four sections, thus giving the area a dressing once in four years. The other years give artificial fertilisers. Where it is possible to fertilise with farmyard manure annually, it is recommended to add approximately ½ cwt. super. Another very important method of fertilising as well as increasing the organic material is by green manuring. Instantly difficulties arise, but I think with judicious work many can be overcome. I refer to the benefits obtained during 1914 by Mr. C. T. Jarman. In his paper on March 15 he stated that the ground was very hard and difficult to plough, the peas were only partially covered. Part of the vinyard was not green manured; it ploughed nicely, and everything pointed to the green manuring being a failure; but the results were overwhelmingly in favor of green manuring, because they were the only vines to carry grapes right through the season. The points to be considered under green manuring are whether the crop used will supply bulk enough and whether it will be far enough advanced to be ploughed under and rolled before the dry weather sets in. The type of crop most suitable is obviously one from the legume family—*e.g.*, peas, beans, lupins, etc. These are most suitable because of the presence of bacteria in the root nodules which flourish on the nitrogen from the air, converting it into valuable plant food instead of in the case of barley and other plants which use the nitrogen already in the soil. The time to plough under is very important. This is done when the peas are in full flower and hence at the top of their development. It should be done before winter rains are over and when there is still sufficient moisture in the soil to enable the green material to change into humus. If this operation is delayed until the soil is too dry, ploughing is difficult, and the green material will largely undergo dry rot instead of becoming humus. To plough under, roll, harrow or tramp the crop in order to bury it properly, it is advisable to use a disc coulter and chain on the plough. Green manuring, however, is not so suitable where rapid growth of the green crop is prevented, and this brings us to the consideration of the rapid growth made by barley, which is not as good as peas, but a good substitute. *Wine Mare*.—I am afraid this method of returning part of the material to the soil is far from properly used in this district. From the figures previously quoted it will be seen that the residue contains a high percentage of nitrogen and should be returned whenever possible to procure. It is recommended that this substance should be mixed with a little lime or gypsum. It contains twice as much nitrogen and about the same amount of phosphate and potash. Too much stress cannot be laid on this method of manuring, and I would advise members strongly to secure as much of the skins, stalks and seeds as possible from the winery. *Most Suitable Form in which to Apply Artificial Fertilisers*.—Here again I refer to Chauzit, a French investigator. He gives the order of preference for the application of nitrogenous manures as follows:—1. Dried blood and nitrate of soda—mixture. 2. Wine mare and nitrate of soda—mixture. 3. Dried blood. 4. Nitrate of soda. 5. Wine mare and ammonium sulphate. 6. Ammonium sulphate. 7. Cyanamide. For economic reasons I should say apply wine mare and ammonium sulphate. Phosphates are best applied in the form of super or basic slag, or finely crushed rock phosphates. *Potash*.—Chauzit gives the following order of preference for potash manures:—Carbonate of potash—in ashes. Nitrate of potash—ordinary saltpetre. Sulphate of potash. Muriate—chloride of potash. Sylvinit—crude salt from Stassfurt. Under these conditions, the carbonate is the best potassic manure, but for economic reasons the sulphate should be preferred. *Lime*.—Most soils contain enough lime to provide the vine's food requirements, but as green manure crops bring more acid into the soil, it is recommended to add ground limestone or ordinary marl. In this form the lime is not washed out of the soil so readily as slaked or quicklime, nor does it destroy the humus in the soil so quickly. Perold recommends a dressing of three-quarters of a ton per acre of limestone every fourth year. *Time to Manure*.—For farm yard manure, the old Italian proverb holds good—"Better a shovel of dung at Christmas than a cartload at Carnival"—thus showing that its effect is not immediate and should be applied during the early winter. Mr. Castella suggests that the crop of one season has been largely built up from the manure applied 18 months previously. The vine absorbs almost the whole of its phosphate and nitrogen in the big rush of growth before the blossoming in October. Later on this is distributed as required. Potash absorption continues later; nevertheless, the whole year's manurial application should be made before the vine starts its growth. From this it is best to manure during winter, at the time of ploughing, or before. *Manuring Fruit Trees*.—Manuring fruit trees is not an old practice; it has not so far received a great deal of attention, and exact records are very difficult to obtain. Experiments have been carried out at Blackwood, but the results have not been published. However, the tree should give the observing grower hints as to its needs, and if the

growth of wood and color of foliage are such as to obviously indicate health and vigor, it may safely be taken for granted that all the tree needs is good management, good cultivation, and judicious pruning; but when a tree has received good attention in this respect and still fails to mature a crop of well-developed fruits and make a satisfactory wood growth, and usually at the same time shows signs of distress in the color of its foliage, it needs help; but the grower must first make sure that the trouble is due to insufficient food supply and not to some other cause such as lack of moisture, or too much of it, fungus, diseases, &c. With trees an element of uncertainty comes in, in the different depths to which various tree roots descend. It has been noticed that different kinds of trees of the same kind vary in the depth to which they behave in this matter, and this has some considerable bearing on the question of food supplies available. A tree which draws a large portion of its food supplies from the subsoil is to some extent insensible to the richness or otherwise of the surface soil, and will respond less readily to any application of manures applied there, and it has been stated by Professor Pickering that the chief factor governing the level at which roots flourish appeared to be more dependent on aeration of the soil than on the food supply in it. At the Blackwood Orchard no particular treatment has given consistently the best results, though it is very evident that all tests receiving nitrogen show to advantage over those not receiving nitrogen. From some figures made up it shows that trees receiving nitrogen are yielding more bushels per acre than those receiving any other dressing. In a season like last, with a shortage of rain, the manured trees did not develop their fruits early as well as those receiving nitrogen. Super alone does not give any results, and the same may be said of potash, but super and sulphate of ammonia together have given best results. Trees receiving nitrogenous manures alone have also carried better crops on the whole in the light season than trees not so treated. It is the experience of most growers of fruit trees and vines that trees assisted in the dry seasons produce better quality fruit than those unmanured. In the growing of wheat we find that the difference between manured and unmanured is a far greater percentage than in the best seasons. Mr. J. M. Ward, Superintendent of Horticulture, recommends the following dressings:—Plums

## THE SUNSHINE HEADER HARVESTER

**ADELAIDE.**

and prunes—Amm. sulph. or sod. nitrate, 1cwt.; sulphate of potash, 1cwt.; superphosphate, 3cwt. Peaches—In autumn: 2cwt. bonedust; in spring: 2cwt. superphosphate, 1cwt. amm. sulphate, 1cwt. sulphate of potash. Professor U. P. Hedrick, of America, in a bulletin entitled "Twenty-five Years Manuring of Apple Orchards," comes to the conclusion that apple trees which had been dressed every year throughout that period with various dressings of artificial and farmyard manures show no appreciable advantage over trees which had received no dressings at all; but one experimenter puts it that manuring has not made good trees into super trees, but it has made poor trees good or kept good trees from becoming poor.

#### EUDUNDA (Average annual rainfall, 17.19in.).

Meeting held September 1st. Present: 11 members. The annual report was presented by the Secretary, Mr. L. Duldig, and a programme of meetings arranged for the year ending June, 1931.

#### HOYLETON (Average annual rainfall, 17.56in.).

The annual meeting was held on August 25th, there being present Mr. C. Sandow (Chair) and 17 members. The report of the year's work was presented by the Secretary (Mr. W. Chapman) and officers elected for the ensuing year.

#### OWEN.

August 29th.—Present: Nine members.

POULTRY.—In the course of a short paper on this subject Mr. F. W. Rogers stated—"In breeding fowls for market, home consumption, or egg production, it is necessary to provide comfortable quarters for the birds. The size and shape of the house can be arranged according to local conditions, but one point is very important, it must be rainproof and free from draughts. For this purpose galvanized iron, with clean timber on cement concrete walls with an iron roof, is recommended if the house is built reasonably high. Iron is a rapid conductor of heat and cold, but if the house is not less than, say, 7ft. high in front with 1ft. fall to the back the birds will be comfortable. The house should be open to the north or north-east, in order to admit as much sunlight as possible. Another important point of the poultry home is the floor, which should be raised 10in. to 12in. above the ground outside, and if it is to be a permanent fixture, cement or asphalt will make a good floor if laid down reasonably. It will be neat and easily cleaned. If the house floor is not kept dry and sweet the whole atmosphere becomes impure. I prefer swinging roosts made with timber that can be formed into a square and hung by light chains from the corner to the sides of the house. This can be rapidly unhooked when cleaning up the floor, and vermin cannot readily travel over the chains. The mongrel or barndoor type of fowl is not worthy of consideration, the pure-bred bird giving more pleasure to the owner and more profits in the egg box. If poultry are to be kept profitably they require good housing and good, wholesome pure food; on no account should mouldy or unsound grain be fed; animal and green foods are necessary adjuncts, although the bulk of the food should be grain, either whole or ground. Regarding breeding, it is a waste of time and expense in trying to breed from other than good, healthy, and sound stock. By selecting a strong, vigorous cockerel (not less than 10 months old) and mating with about six two-year-old hens of good type, hatches of sound, strong, healthy chickens should result. For egg production any of the Mediterranean breeds are good, for instance, White or Brown Leghorns, Minorcas, Andalusians, or Hamburg are among the best; my preference being White Leghorn or Minorca. One cannot go far wrong if the Black Orpington is selected, because, unlike the lighter breeds, they do not worry stables, haystacks, &c. If a certain cock bird has produced a good line of pullets that have matured early and given eggs of good average size and shape, select a few of the best pullets that are the most prolific layers and mate them back with the old bird, and in all probability one will get better layers from the second year's mating than with the first. To maintain a high standard in the flock vigorous culling and breeding only from the best birds are essential." During the discussion Mr. Bowyer thought cement floors too cold during winter, whilst in reply to questions regarding crossing Mr. Rogers advised crossing back but once, and favored two-year-old pullets. Mr. Bowen thought it a wise plan to use angle iron in place of timber, small fires could then be lit inside the fowl houses and all vermin would be destroyed or driven out. Mr. Lake stated that old tractor or car lubrication oil, if used freely, would eradicate and destroy tick and other vermin. He favored using the oil as a paint—all woodwork, especially joints, to receive a liberal application. Mr. Helps did not favor the pure-bred fowls, as a rule they were too delicate, and the half-bred would withstand more hardship. Mr. McPharlin agreed that the pure breeds were much more delicate, but believed they warranted the extra care. (Secretary, Mr. A. Bowyer.)

**RIVERTON** (Average annual rainfall, 20.86in.).

The Chief Dairy Instructor (Mr. H. B. Barlow) addressed the meeting held on September 8th on the subject, "The Dairy Act." There were present 10 members and six visitors. (Secretary, Mr. O. Longbottom.)

**SADDLEWORTH WOMEN'S** (Average annual rainfall, 19.65in.).

The annual meeting was held on August 19th, there being present 14 members. The annual report was read, officers elected, and a programme of meetings arranged for the ensuing six months. Members reported having visited the Auburn Women's Branch on the occasion of Miss Campbell's lecture. (Secretary, Miss D. Partridge.)

**SADDLEWORTH WOMEN'S** (Average annual rainfall, 19.65in.).

September 9th.—Present: 10 members and two visitors.

**FANCY WORK HINTS.**—The meeting was held at the residence of Mrs. J. Frost. The following paper was presented by Miss E. Frost:—"Colored Embroidery.—Colored embroidery is very effective, and some pretty designs can be obtained either on white linen, colored crash, or colored linen. Small designs look very nice worked with one strand of stranded cotton; larger designs with two, three, or four strands cotton A'Broder, or pearl cotton. White embroidery, crochet, tatting, also the old fashioned hardanger canvas, punch work, Mount Mellick work, are all serviceable and launder beautifully. When the Victorian Better Farming Train was at Riverton last year there was a lecture on dressmaking and fancy work. One thing that attracted attention was the sugar bag cushions. The sugar bags are dyed with permanganate of potash, and then worked with fancy stitches in colored wool, either embroidery stitches or cross stitch. *Crochet*.—Crochet should be done evenly. It loses half its beauty in appearance when finished if some trebles are longer than others, or some chains or doubles are done loosely. Another important point is to always use a needle to correspond with the thread, a small needle for fine thread and a larger needle for coarser thread. Use a No. 7 crochet hook for fine cotton for working d'oyleys and handkerchief edgings, and a No. 4 or 5 hook for coarser crochet cotton, fibron or any other thread of about that size. For d'oyleys 80 Mercer crochet cotton may be used, or preferably, perhaps, 100. Sandwich d'oyleys are effectively crocheted in 150 Mercer cotton, and also handkerchief edgings. Crochet should always be ironed on the wrong side when laundered, and pulled into shape before being pressed. *Tatting*.—The thread used in tatting is very important in the appearance of well-finished work. It must be firmly twisted, smooth, and even. Colored tatting is charming when it harmonises with colored work. Tatting is easily soiled when working; the work is held firmly with the fingers, so always be careful to have clean hands when starting. Care should be taken in joining. Always join cotton at the finish of a ring, and be careful not to tie a "granny's" knot. The ends must be cut off close to the knot. When working with two threads, the ball and the shuttle, it is best to have another ball of the same thread to refill the shuttle, to avoid breaking the thread on the ball. Tatting, like crochet, must be done evenly to ensure a well-finished appearance. All rings must be pulled tight. In the "Semco Tatting Book" it advises the use of borax in the water when washing. Do not wring with the hands, but squeeze out the soapy water and rinse in two waters. Tatting should be ironed when nearly dry, pulled into shape with fingers, and placed on a well-padded ironing board, covered with a thin cloth, and pressed carefully. Never rub an iron over unprotected tatting. Mercer crochet cotton is suitable thread for this work, and it can be

## SUMMER FODDER CROPS

Now is the time to sow

**SUDAN GRASS, MAIZE, MILLET, SORGHUM,  
LUCERNE, &c.**

— New Seed now Available —

**Charles Whiting & Chambers Ltd.**  
13, PITT STREET, ADELAIDE.

purchased in a number of sizes. *Knitting*.—Knitting also must be done evenly. For fine wool use small needles and larger needles for coarser wool. "Hug-me-tights" are knitted usually on very large needles. All knitting should be pressed lightly on the wrong side, under a damp cloth, when finished. Always see that the pattern is level when making a seam in fancy knitting. To make a firm edge when casting on stitches use two threads. For socks, do not cast on tightly—allow room to stretch. Always graft the stitches together for the toe of a sock. Grafting can be done to look like continuous knitting. *Richelieu and Eyelet Work*.—In richelieu work all bars across where the linen is cut away should be worked first, and fastened into the linen on each side. This is to prevent breaking away, and the button-holing can be done much more evenly. Be sure to catch up the bar when button-holing. In eyelet embroidery it is advisable to cut one or two threads each way. This prevents the linen from "puckering" around the eyelets. Put the stiletto in the eyelet, cut the thread with sharp scissors, and then insert the stiletto lightly once again. (Secretary, Miss E. Frost.)

Meeting held October 7th. Present: eight members. The reports of the delegates to the Annual Congress was received and discussed.

#### WASLEYS WOMEN'S.

August.—Present: 43 members.

*Hot Box Cooking*.—Mrs. C. George read the following paper:—"The hot box can be made at home with a box with a firm fitting lid, which, for convenience, will go under the kitchen table. Pack the box firmly with chaff, and bring the stew, cutlets, porridge, &c., to the boiling point on the stove. Then well wrap the utensil in an old blanket and push it down firmly in the middle of the box of chaff. Cover the lid of utensil with chaff and close the lid of the box firmly. The ingredients in the box will continue cooking and be ready to serve in five to six hours. Porridge can be left over night in the hot box to cook. Miss G. George read a paper, "Fancy Work," and exhibited some finished articles for inspection.

At the September meeting the annual report was presented, and officers elected for the ensuing year, after which a musical programme was given.

The October meeting was attended by 38 members. Reports of the Annual Congress were received, and the meeting then took the form of a Question Box. Members of the Women's Branch also held a combined social meeting with the Men's Branch to conclude a year of successful work. (Secretary, Mrs. M. Wilson.)

#### WILLIAMSTOWN WOMEN'S (Average annual rainfall, 27.84in.).

Meeting held September 3rd. Present: Mrs. Hammatt (Chair) and nine members. Mr. Hammatt gave a rose pruning demonstration and replied to numerous questions. (Secretary, Mrs. G. Cundy.)

### YORKE PENINSULA DISTRICT.

(TO BUTE.)

#### PASKEVILLE (Average annual rainfall, 15.67in.).

September 2nd.—Present: 16 members.

*THE ADVANTAGES OF MEMBERSHIP WITH THE AGRICULTURAL BUREAU*.—Mr. J. Pontifex, in reading a paper on this subject, said, as a life member of the Bureau, he could state that there were many benefits to be derived from an active association with a Branch of the Agricultural Bureau. Mr. Pontifex gave an interesting outline of the early history of the organisation. Continuing, he said that widespread adoption of the practice of bare fallowing could be traced to the dissemination of knowledge through the Bureau. He also made reference to the value of the *Journal of Agriculture* and the advice that could be obtained through its columns. The Agricultural Bureau Field Trial Societies, particularly the Northern Yorke Peninsula Society, had done an immense amount of good in the interests of the man on the land. Too much credit, said Mr. Pontifex, could not be given to the founder of the organisation, the late Mr. Molineux, who evidently foresaw the day when a Department of Agriculture would be established and the value that a system of getting in touch with primary producers, such as the Agricultural Bureau, would be to the State and the producers. The Bureau was an ideal channel through which the department could spread its information. Again the Bureau had proved of incalculable value to the various instructors. It afforded them the opportunity of meeting farmers and other landholders and discussing with them the problems that the man on the land was called upon to face. Despite the immense good done by the foregoing, Mr. Pontifex expressed the opinion that the best work of the Bureau was undoubtedly the mutual help which farmers gave one another through being members of the institution, and that alone should induce all producers to become members. The papers read at different meetings were published and so

brought under the notice of Bureau members all over the State. Country Conferences further enhanced the value of the Bureau and widened the views of its members as well as of the officers of the department who attended. In many ways, too, the Bureau sought to safeguard the interests of producers, and was the connecting link between members and the Government. As a means of propaganda for the latest advances in all matters pertaining to agriculture as a whole, the Bureau was a most important factor. In any form of educational work there could be little success without organisation, and the Bureau supplied that very necessary feature. The greater the membership the more efficient would the institution become and the greater would be the opportunities for farmers to gain first hand knowledge on matters in which they were so vitally interested. (Secretary, Mr. J. Prouse.)

#### SOUTH KILKERRAN.

September 2nd.—Present: Nine members and visitors.

**IMPROVING THE FARM FLOCK.**—Mr. R. Hastings read the following paper:—"It is an accepted principle in sheep breeding that improvement begins when the flockowner decides to use pure bred rams of the breed found to be most suitable for his district. If all owners of small flocks followed this rule instead of using rams, the breed of which they know little or nothing about, they would soon have sheep showing similar type, quality, and grade of wool. Well bred sheep eat no more, and often less, than nondescripts, and on that score alone they must be more profitable. To get the best results the ewes must be carefully culled, and there is no better time to do this work than at shearing time, or just before. Then the animals that are bad doers, carry faulty fleeces, are weak in constitution can easily be detected and a cull mark put on them. Particular care should be taken to see that the ewes have sound, good udders and perfect teats. In shearing, many lambs have their teats injured and later cannot suckle a lamb properly. The cull ewes should be fattened and sold for slaughter. By regular culling and disposing of all the objectionable ewes, and keeping all the best ewe lambs instead of selling them, the flock will steadily improve on the soundest lines. To get the best results from such ewes, the rams should always be typical of the favored breed. In buying rams it is advisable to purchase direct from the breeder 'in the wool.' This in itself is a guarantee regarding their breeding and the class of stock they are likely to throw. Buyers of shorn rams at country sales often pay higher prices than they would have paid for better sheep in the wool direct from the breeder earlier in the season. Wool, shape, and constitution are the three necessary points the buyers of rams have to consider, and those who neglect to buy early cannot expect to get rams of the best type, seeing that the pick are always sold first. Every breed has its special qualities, and each does well when kept under conditions suitable for its proper developments." (Secretary, Mr. N. Schrapel.)

#### THEINGTON.

The monthly meeting of the Branch was held on September 9th, and was attended by 19 members and visitors, including Mr. W. Johnston (District Agricultural Instructor). Papers on the subject, "Horses v. Tractor," were contributed by Messrs. C. Rodda and E. Yelland. A keen discussion followed. (Secretary, Mr. S. Chynoweth, Kadina.)

#### UPPER WAKEFIELD.

The inaugural meeting of the Branch was held on September 4th, there being present 25 members. Officers were elected and a constitution for the working of the Branch was agreed upon. (Secretary, Mr. J. Hartnett, Upper Wakefield, *via* Halbury.)

### WESTERN DISTRICT.

#### CALCA.

August 6th.—Present: Nine members.

The meeting discussed the advantages of fallow competitions. Some members were of the opinion that this district was unsuitable for fallow competitions, owing to the changeable soil; but after the conditions of judging had been explained, it was resolved that a competition be held. (Secretary, Mr. J. Cash, Mortana.)

#### CARALUE.

Meeting held August 6th. Present: 12 members. Several subjects of local and timely interest were brought forward, and profitable discussion ensued. (Secretary, Mr. E. Marshall.)

CLEVE (Average annual rainfall, 14.63in.).

September 4th.—Present: Nine members.

**PLANTING A FRUIT GARDEN AND VINEYARD.**—The first point that should receive consideration in laying out a fruit garden, said Mr. G. Hauschild in the course of a paper on the above subject, was the selection of a site. This should consist of a block of land with red, loamy soil overlying a clay subsoil. Six months before planting the land should be broken up to receive the benefits of the early rains and then broken down to a fine tilth. Care should be taken to see that the trees and vines were planted in straight lines. For a farm garden he favored planting at a distance of 20ft. by 20ft., so that a horse could be worked comfortably between the rows. Holes should be sunk 2ft. by 2ft. by 1½ft. deep, the bottom soil loosened with a pick, the hole refilled, and then a hole made sufficiently large to take the tree with its roots spread out. The trees should be planted at the same depth as in the nursery. The soil should then be pressed down around the tree, taking care to hold the tree so that it did not sink too deep. A bucketful of water applied immediately would help to pack the soil around the roots of the tree. After the water had soaked away the surface soil around the tree should be loosened. Fruits recommended for the district were apricots, peaches, plums, and figs. Apples would do well if planted where water could be drained on to them. The vines should be planted 20ft. by 10ft. apart in a hole 18in. by 18in. by 18in. deep. Varieties favored by the writer were Black Prince, Muscatel, and Doradillo. (Secretary, Mr. H. Matthews.)

#### COLLIE.

The annual meeting was held on August 7th. A report of the year's work was tabled and officers elected for the ensuing 12 months. (Secretary, Mr. D. Gunn (Mount Cooper).)

ELBOW HILL (Average annual rainfall, 11in. to 12in.).

August 6th.—Present: 14 members and six visitors.

**CO-OPERATION.**—In the course of an address, "The Benefits of Co-operation," Mr. G. Payne explained the growth of co-operation throughout the world during the last decade. Russia, China, Argentina, and the United States of America had all adopted co-operation methods in buying and selling practically every commodity for the benefit of their members. Great Britain supplied the wants of nearly half of its huge population through its various co-operative societies. He dealt fully with the marketing of wheat through co-operation. (Secretary, Mr. W. Cooper.)

GOODE WOMEN'S (Average annual rainfall, 10.20in.).

Fourteen members and 14 visitors attended the annual meeting of the Branch, which was held on August 7th, and the report of the year's work was presented by the Secretary, Mrs. A. Watson, of Ceduna. After formal business had been transacted, the meeting took the form of a social evening. Delegates were present from Maltee and other neighboring Branches, and a most enjoyable evening concluded with dancing and supper. Mrs. Fagan donated a cake, a piece of which was handed to each member, in recognition of the first annual meeting of the Branch.

GOODE WOMEN'S (Average annual rainfall, 10.20in.).

The meeting of September 10th was attended by 10 members, and took the form of a Question Box. Subjects discussed included "Bread-making" "Preparation of Yeast," etc. (Secretary, Mrs. A. Watson, Ceduna.)

GOODE WOMEN'S (Average annual rainfall, 10.20in.).

Ten members and visitors attended the meeting held on November 5th, at which general business was transacted.

A meeting was also held on October 8th. Mrs. D. Fogan presided over an attendance of seven members. Mrs. Fogan and Miss C. Peach reported on the Adelaide Congress. Miss E. Campbell (Dip. Dom. Econ. of the Education Department) delivered an address, "Diets in the Home." (Secretary, Mrs. A. Watson.)

GREEN PATCH (Average annual rainfall, 26.56in.).

September 4th.—Present: 15 members.

**EARLY FODDERS FOR SHEEP.**—The monthly meeting was held at the residence of Mr. E. Chapman. In introducing the above subject for discussion, Mr. Sinclair said there was always difficulty in preventing sheep from losing condition during the early part of winter. He had tried the practice of understocking some of the paddocks during the previous year in the thought that the high, dry grass would protect and encourage the growth of early feed, but it had not proved successful. Mr. A. Schwerdt favored

sowing rye and oats in April in the previous year's stubble, and that usually provided early feed for the sheep. Most members favored the practice of drilling in oats and barley very early on the stubbles aided by hand feeding on chaff. Mr. S. Baillie stated he had had good results from kale for winter feeding. It was generally agreed that more attention should be paid to the growing of lucerne. (Secretary, Mr. C. Whillas, Port Lincoln.)

**KOPPIO** (Average annual rainfall, 22.40in.).

Meeting held August 12th. Present: Mr. W. Cooper (Chair), eight members, and two visitors. The Secretary read an article dealing with the harm done to horses and tractors by overloading. (Secretary, Mr. M. Gardner.)

#### PINBONG.

August 9th.—Present: 12 members.

**FALLOWING.**—The meeting was held at the residence of Mr. A. Scholz. Mr. A. Scholz read the following paper on the subject, "The Advantages and Disadvantages of Fallowing in this District":—"This district still being in its infancy, most farmers have not yet been able to adapt themselves to systematic farming. Land cannot be continually cropped without spelling the land and fallowing. The advantages of fallow are well noted in all districts by yield reports, therefore it is essential to fallow, to give the land every possibility of yielding as much as possible. Plough the soil about 3½ in. to 4 in. deep in June and no later than the middle of July. Do not try and fallow in September and October and expect good results. Plough the soil when it is in a wet condition, irrespective of weeds; weed killing can be done with the cultivator in a later operation. The main object of fallowing in this district is to conserve moisture so that in the following year the growing crop has sufficient moisture to resist any dry spells which are apt to check its growth. After the soil has been ploughed in June and then cultivated towards the latter end of July, and good rains are favorable in August, I suggest cultivating it again. *Disadvantages of Fallow.*—The soil not having enough clay in it, causes no end of trouble trying to keep the fallow in the right paddock and keeping the fences from being drifted over. Farmers often turn a flock of sheep on the fallow to cope with the few weeds which the implements have not destroyed. This is a mistake, because the few little clods and rough surface of the ground soon becomes powdered by the hoofs of the sheep and it is impossible to hold the drift. Even if the paddock is cultivated again, the soil being fine is soon levelled again by the severe winds. The only way to prevent the soil from drifting in this district is to leave a certain amount of stubble in the paddock chosen to be fallowed. Never burn the stubble in the paddock that is to be fallowed or have it eaten out bare with a flock of sheep. When a small amount of stubble is turned in with the plough and worked up again with the cultivator it breaks the sweep of the wind. After the three operations mentioned have been completed, harrow the paddock after a further rain. This will pack the loose soil, bring the tiny clods to the surface, and be a further preventive of drift." (Secretary, Mr. C. Scholz, Yaninee.)

#### PINKAWILLINIE.

The meeting of August 9th was held at the residence of Mr. W. Miller, there being present eight members. An interesting paper, "Tractors, Trucks, and Travellers," was read by Mr. Halliday. (Secretary, Mr. S. Johnson.)

## M. F. HODGE, A.C.I.V.

**LICENSED LAND VALUATOR AND AGENT,**

**42, GRENELL BUILDINGS, GRENELL STREET, ADELAIDE.**

Phone: Cent. 2861. .. Private: 944-2867. .. Telegrams: Matthodge, Adelaide.

**SPECIALIZE IN COUNTRY VALUATIONS.**

**LOWEST QUOTES FOR ALL GRASS SEEDS.**

**LUCERNE AND CLOVERS ALWAYS AVAILABLE.**

**EXPERT ADVICE ON GRASSES AND CLOVERS.**

## PYGERY.

September 2nd.—Present: 23 members and three visitors.

**HINTS CONCERNING MALLEE FARMING.**—In the course of a paper under the title "A Few Errors Common to Farming in the Mallee," Mr. E. Day said the most common mistake was the continual sowing of large areas of wheat. Better worked smaller areas, in conjunction with a good rotation, should ensure more reliable returns. In other than drought years they could grow oats, barley, or peas, which could be profitably fed to stock. Lucerne, Wimmera rye grass, and other fodder crops, with the yearly growth of grasses and weeds, would enable them to carry a large number of stock. In putting their dependence solely in wheat and wool they were taking too great a risk. No other country in the world depended on such a meagre diversity of products from the land. The success or failure of the wheat crop to a large extent determined the financial solvency of both the farmer and the country, and as so many adverse influences affected the chances of a full crop of this product, their assurance of financial stability was far from strong. Farmers were prone to plant large areas each year, often on land previously carrying the same crop, instead of smaller better worked and manured areas, grazing or some other crop always to follow wheat. Another error was to discard a good wheat that had done well over a number of years for a new one that had suddenly given a heavy yield in some other district. It might be quite unsuitable under different conditions, besides possibly introducing some disease. Again, one sometimes heard the statement that wheat would deteriorate if grown in one district too long, but with care in selection and keeping it free from other varieties it would rather improve year by year. Many farmers failed to conserve sufficient reserve stocks of fodder from good years to carry stock over the dry periods. Other mistakes made were keeping stock after it had reached its best marketable age and condition, the cutting down of thousands of acres of magnificent mallee, titrees, or pines containing fine fencing posts which were burnt in the hurry to clear the land. Noxious weeds could often be prevented from getting a hold on the farm by destroying perhaps only one or two odd plants on their first appearance. Wild mustard (although a bad weed in a crop) was a useful fodder plant. Discussing the paper, Mr. Humphries did not favor growing wild mustard as a fodder crop. Mr. Symonds agreed that farmers should store more reserve fodder for stock, and believed in better cultivated and manured smaller areas. Mr. E. Edmonds considered that wheat would always be the main line of production. He thought they should conserve all cocky chaff and grow more oats, and store them loosely in a shed just as they were reaped with the stripper. Mr. W. Heath said the farmer should put in as large an area as possible and thereby get his holding cleared as soon as possible. (Secretary, Mr. E. Day.)

## ROBERTS AND VERRAN.

August 6th.—Present: 14 members and eight visitors.

Mr. H. D. Adams (District Agricultural Instructor) gave an address, "Control of Sand Drift." Mr. Adams also gave a demonstration with the Babcock milk tester. (Secretary, Mr. C. Masters.)

**FODDER CONSERVATION.**—At the July meeting the following paper was read by Mr. M. Masters:—"Dry seasons have again brought home to producers the necessity for conserving fodder in good seasons. Every farmer should sow at least 10 acres of fallow with oats for every working horse kept. Stubble land should be sown with oats, sowing at least 1 bush of seed per acre, preferably Algerian, as these stand rough conditions better than other oats. As much hay as possible should be cut every year, and what is not required for the following year should be stacked separately, mouse-proofed, and covered with straw. Always put plenty of straw on to make sure that the rain does not soak in. Straw should be cut and stacked whenever possible and salt sprinkled on each layer. Where a large area of oats suitable for hay is grown, a portion should be cut green and chaffed immediately into a pit and ensilage made of it. This is a very valuable fodder; it retains the green feed properties and is ideal for feeding to stock during the summer. A pit 10ft. deep and 20ft. in diameter should accommodate 30 tons of ensilage. Ensilage will not burn and will store for an indefinite period. Any green feed can be cut or used and stored in bulk, but chaffed fodder is preferable. All cocky chaff should be saved and covered with straw. If covered properly it will keep for years. A large straw shed should be provided and filled each year, away from stables in case of fire. If ensilage is conserved and cocky chaff saved, they can be fed to stock, and especially to ewes and lambs. The cocky chaff for bulk and the ensilage having the green-feed properties, will be excellent in the absence of the green feed in the paddocks. All stock should be paddock-fed as much as possible in order to save the conserved stocks of hay, cocky chaff, or ensilage. If these few items are put into practice there should be little trouble through feed shortage."

**STREAKY BAY** (Average annual rainfall, 14.95in.).

Nine members attended the meeting held on August 15th. Matters of local and timely interest were discussed. (Secretary, Mr. C. Thom.)

**TALIA.**

The monthly meeting of the Branch was held on August 11th, and was attended by 22 members and three visitors. The annual report was presented and officers elected. Mr. W. Brownrigg (District Instructor) delivered an address, in which he dealt with various phases of farm activities. (Secretary, Mr. A. Thompson, Elliston.)

**TALIA** (Average annual rainfall, 15.27in.).

Mr. F. Elliot presided over an attendance of 11 members at the meeting held on August 29th. Members reported considerable trouble with the blowfly pest in sheep, and several useful home-made remedies were suggested. (Secretary, Mr. A. Thomson.)

**TARAGORO.**

Meeting held September 4th.—Present: 14 members and four visitors. An instructive paper, 'Farm Management,' was contributed by Mr. A. Crooks. (Secretary, Mr. T. Winters, Cleve.)

**WALLALA.**

August 13th.—Present: 13 members and visitors.

**PIGS AS A SIDE LINE TO WHEATGROWING.**—Mr. J. Thompson read the following paper:—'*Selection of Pigs.*—Secure as near pure-bred stock as possible for breeding purposes, and favor a Berkshire boar mated with a Tamworth sow. Select a sow with at least 12 teats, and whilst she is developing do not allow her to become too fat. *Care of Sow and Young.*—If possible provide the sow with the run of a small paddock until about two weeks before farrowing, then it is best to shut her up away from the other pigs. On no account overfeed the brood sow; if she is too fat she will become clumsy and is likely to kill the young pigs. After farrowing give the sow three small feeds a day. Skim milk and crushed wheat is a suitable feed for the first two or three days after the pigs are born. When four weeks old the young pigs should be provided with a trough, out of which they can feed themselves. Warm quarters in winter which can be well ventilated in summer are essential to the good health of the sow. On hot days water can be poured on the ground to assist in keeping the pigs cool. A young sow should not be mated until she is at least 12 months old. Best results will be obtained if regular feeding hours are observed. I feed boiled wheat and water. Allow a 6lb. tin of wheat to each pig of about six months of age. Do not stint the young pigs in their feed. When the pigs are ready for topping up feed them as much as they will eat. Charcoal should be allowed two or three times each week, it helps to keep the pigs healthy. A pig at eight months old weighing 180lbs. to 190lbs. will nearly always find a ready sale. The paper concluded with cost of feeding and sending the pigs to Port Lincoln. (Secretary, Mr. C. Zippell.)

**WIRRIILLA WOMEN'S.**

September 5th.—Present: 10 members.

On the occasion of the annual meeting the election of officers took place. Mrs. Blatchford supplied the following recipe for soap making:—6½lbs. fat, 2galls. water, one tin caustic soda, ½lb. borax, ½lb. resin. Simmer for two hours, and when cool add two cupfuls of kerosene.

The meeting of October 2nd was held at the residence of Mrs. Blatchford, there being present 12 members and three visitors. A lengthy and instructive report of the proceedings of the Annual Congress was tendered by Mrs. Woods.

**PUFF PASTRY.**—The following recipe for making puff pastry was supplied by Mrs. Blatchford at the meeting held on November 5th:—Take equal quantities of butter and flour and a pinch of salt. Sift flour and add one teaspoonful of lemon juice, or, failing the latter, as much cream of tartar as will lie on a shilling. Mix the ingredients to a pliable dough with cold water. Flour a cloth, place the butter in it, and roll to remove as much moisture as possible. Then place it in the centre of the dough, which has been rolled into a square. Fold same over and put away in a cool place for at least a quarter of an hour, and then roll out, fold, and put away again. This should be repeated three times. Finally, roll, but not too hard near the edges of the paste. Cook in a hot oven. Fifteen to 18 minutes will be required for tarts. Keep everything as cool as possible whilst handling the paste. (Secretary, Mrs. W. Jones, Auburn.)

## EASTERN DISTRICT.

## (EAST OF MOUNT LOFTY RANGES.)

ALAWOONA (Average annual rainfall, 10.20in.).

August 25th.—Present: 11 members.

**LAMB MARKING.**—In the course of an address on this subject Mr. Burnett, of the Caliph Branch, recommended marking lambs when they were from three to five weeks old. For the operation of marking he recommended the knife. The end of the purse should be removed to provide for proper drainage of the wound. For earmarking six different marks were required—one for each of six years—marking ewes on the off side and wethers on the near side ear. Replying to a question, Mr. Burnett said the Brands Act stipulated that it was not legal to take out more than  $\frac{1}{2}$  in. to  $\frac{3}{4}$  in. from the ear. It was stated that a farmer could choose his own design for an ear mark. Mr. Burnett mentioned that he did not favor the removal of the testicles with clams. (Secretary, Mr. B. Flint.)

## BERRI.

September 8th.—Present: 20 members.

**UNDERGROUND DRAINAGE.**—Mr. H. Garde, B.E., of the Irrigation Department, read the following paper:—“*Seepage.*—Seepage is caused by the accumulation of surplus irrigation water, after an irrigation, when the natural drainage is defective, and can only be removed by underground drains. This is the simplest case to deal with, and in every one that has come under my notice, where vines and trees have been affected by a rising of the water table, an immediate improvement has been effected by the laying of a drain. *Salt as the Result of Seepage.*—This is a more difficult problem to deal with, and is caused by growers failing to attend to seepage patches. It is due to a gradual concentration of salt which has been taken into solution by the action of water passing over salty country. Where the natural drainage is defective, this salt-laden water accumulates, rises to the surface by capillarity, is evaporated, and the salt is left behind on the surface. So it is necessary for all irrigationists to test immediately any suspected seepage patches, and if there is water showing, to immediately instal a system of drainage before the point is reached when the salt begins to concentrate more on the surface. *Salt.*—Portion of the Murray lands are naturally salty, and these are most difficult to deal with, because the impervious clay is generally very close to the surface, which makes good drainage almost an impossibility. The cause of the land becoming affected with salt at an early stage is as follows:—Irrigation water which may be quite free from salt if poured on to this land, and the water sinks down to the clay, at the same time taking into solution the salt contained in the surface soil, as well as the subsoil, with the result that a solution heavily charged with salt has accumulated on that clay. This salt solution rises to the surface by capillarity, the water disappears as vapor, and the salt remains on the surface as in case two, but in larger quantities, and the only means of recovering land of this class is by flooding and intense drainage. The effect of seepage on trees and vines is a spindly growth, falling off of crop, and general weakening of the plant until death ensues; the effect of salt as the result of seepage is similar to seepage, but with characteristic blackening and curling of the edges of the leaves. The most effective method of dealing with seepage or salt is by underground drainage, and I advise all growers in this area to keep a watchful eye on any suspicious patches and immediately try those patches by test holes or trenches. The latter are generally very inconvenient on a fruit block, and test holes are more often adopted as the most convenient method of investigation. Several of these test holes should be put down in any suspected spot and lined with down piping. Any change in soil should be noted, and the clay depth accurately determined; water level noted 24 hours after boring when the watertable will have reached its correct level; and the rise and fall of this watertable observed during and after irrigation. For an extended seepage area, several test holes put down at regular intervals in 1 to 1½ square chains are necessary, so that a contour of the impervious claybed can be determined. This is absolutely essential before an efficient scheme of drainage can be evolved, for it is impossible from surface indications to locate the most effective position for the drains. These holes are generally bored to a depth of 6ft. or 7ft. or to the clay-bed. The locations of these test holes are then plotted on a plan, the clay contour determined, any depressions or bars noted, and a design prepared to give the maximum effect. The drainage scheme is then pegged out on the ground, levels are taken at each chain, and grades worked out, keeping in mind the clay depths obtained in the test holes to determine the depth to which the drain-tiles are to be laid. In the work in this area a standard of 5ft. has been adopted, but this is varied according to the results obtained in the test holes.

**Methods of Construction.**—The first consideration is an outlet for the drain water. This consists of (1) a direct outlet to the river flats; (2) a main drain to the river; (3) a seepage shaft; (4) a seepage bore. Direct outlet to the river is very satisfactory, and consists of a sump on the boundary of the block, and either tiles or pipes leading to the flats at such a length as to provide a good getaway for seepage water. **Main Drains.**—These are mostly constructed of concrete pipes, and have been installed where a fall can be obtained to the river. Sumps are constructed on these mains—generally on the lowest point of each block encountered for the purpose of collecting drainage water from the blocks, settling silt, and for observation purposes. **Seepage Shafts.**—Where no main drain is available, seepage shafts have been sunk to drainage sand, which is struck at approximately 40ft. in the Berri area. These shafts are close timbered in with 6in. x 2in. jarrah, and are 4ft. x 2ft. in the clear. A ladderway is built down each shaft, and a heavy door provided. A sump is constructed either of timber of the same dimensions as the shaft or of 30in. reinforced concrete pipe, and connected to the shaft by 4in. or 6in. reinforced concrete pipes. The block drains are connected to this sump, which serves the purpose of collecting any silt contained in the block drainage water, and prevents it from fouling the sand in the shaft. In most cases these shafts have proved very efficient, but they require cleaning out periodically. **Seepage Bores.**—Where it has been found impossible to sink a seepage shaft, owing to the nature of the country, 4in. bores have been put down to drainage sand. These are not so satisfactory as shafts, owing to the very restricted drainage area afforded by a 4in. pipe, but with care and attention they will deal with an enormous amount of water. **Block Drains.**—The block drains after the grades have been determined are commenced at the lowest part of the block, the trench is excavated to within 3in. or 4in. of the final depth, and pegs are then bored in to the correct depth or grade 4ft. or 5ft. apart, and the last 3in. or 4in. of soil trimmed off to the level of these pegs, leaving the bottom of the trench true to grade. The tiles are then laid on this finished bottom, the joints covered with strips of tarred or waterproof paper for two-thirds of the circumference, and the tiles consolidated with earth to prevent any displacement; a No. 10 galvanised wire is drawn through the tiles as the laying proceeds. These wires are for cleaning purposes, and should be pulled through at frequent intervals to prevent the accumulation of silt in the tiles. In salty ground these wires should be renewed every 12 months, because the salt water eats them away. Where the trench is in soft ground, it is impossible to peg the bottom, and each tile is boned in as it is laid. This is the most expensive method of laying, for it requires the services of one man sighting all the time, whereas in the first method the man sighting in the pegs is only needed for a short period, and he can then go on excavating ahead of the man laying the tiles. **Inspection Sumps.**—Inspection sumps, consisting of 18in., 21in., or 24in. reinforced concrete pipes are constructed at 5 chain intervals, or at the bend or junction. These are for collecting silt, the bottom being set 2ft. below the trench line and for observation purposes, and to isolate any section of drain that may have become choked. In soft ground these sumps are set vertically on 6in. by 12in. jarrah. The inlet and outlet tiles are cemented to the sump pipes, and the cleaning wires are brought to the top and fixed to the lid. The diameter of the tiles to be used is determined by the length of the drain and the available grades. Nothing less than a 3in. tile is advisable for grades over 3in. to the chain, and for grades less than 3in. to the chain a 4in. tile is essential. Generally speaking, where a drain is over 20 chains long, the lower half of the drain should be laid with 4in. tiles. **Cost of Construction.**—The cost of construction is, of course, governed by the cost of labor, which represents at the present time approximately two-thirds of the total cost, and as a general rule in estimating labor costs, three men should complete over 1 chain of drain per day in good average ground with a 5ft. trench. It will be seen from the foregoing remarks that drainage is a costly operation, and I advise all blockers who are installing a drainage system to make a thorough subsoil investigation before finally determining the location of such drains, so that they may have the maximum effect over the shortest length of drain, the latter item being especially mentioned from the fact that while salt is being removed from the land, other valuable properties in the soil are also being removed, as well as plant food artificially applied in the way of soluble manures. In conclusion, I would emphasise the necessity for all those who have evidences of salt on their blocks to make an immediate drainage. These plague spots if given immediate attention can be cured in a comparatively short time, while if left to grow they may take years to eliminate." (Secretary, Mr. E. Johnson.)

#### BOOLGUN.

Mr. R. L. Griffiths (District Agricultural Instructor) addressed the meeting held on September 3rd on the subject, "Crop Rotation for the Mallee Areas." There were present 24 members and two visitors. (Secretary, Mr. J. Palm.)

**BRINKLEY.**

Twenty-one members and three visitors attended the meeting held on September 3rd, when Mr. R. Hill (District Agricultural Instructor) delivered an address, "Crop Rotation." (Secretary, Mr. C. Pearson.)

**COOMANDOOK** (Average annual rainfall, 17.45in.).

Mr. B. Crewe, of the Vacuum Oil Company, delivered an address, illustrated with moving pictures, "Petroleum and Its Products." There was a large attendance of members and 50 visitors. (Secretary, Mr. W. Trestrail.)

**COPEVILLE** (Average annual rainfall, 11.58in.).

One of the best meetings yet held under the auspices of the above Branch took place at the residence of Mr. G. Sutherland on September 4th. During the afternoon an attendance of 35, including members and visitors, spent a most instructive afternoon inspecting the departmental plots being conducted on Mr. Sutherland's farm. In the evening an address dealing with the subjects, "Fertilisers," "Wheat Varieties," and "Crop Rotations," was delivered by the District Agricultural Instructor, Mr. R. L. Griffiths. (Secretary, Mr. G. Sutherland.)

**LOWBANK.**

September 3rd.—Present: 13 members and three visitors.

Mr. A. H. Kuchel read a paper on "The Most Suitable Horse for this District." He advocated a medium draught for the district, the heavier horse consumed more feed, whereas the clean-legged horse did the same amount of work with less feed, and the medium horse would stand up to more paddock feeding. A good discussion followed by members, who were all of the same opinion, with the exception of Mr. E. Nitschke, who said if possible one should keep one or two heavy draughts in order to be handy when a strenuous pull presented itself. The lighter horse would need excessive strain to do the same work. (Secretary, Mr. L. Geyer, Waikerie.)

**MAEAMA.**

Twenty-four members and four visitors attended the meeting held on September 6th. Matters relating to the Annual Congress and Crop Competitions were discussed. (Secretary, Mr. T. Hinkley.)

**PINNAROO WOMEN'S.**

October 3rd.—Present: 26 members and visitors.

**VEGETABLE GARDENING.**—Mrs. Hawthorne, who won first prize in the Vegetable Gardening Competition conducted under the auspices of the Branch, read the following paper:—"Choose a position sheltered on the north and western sides. During November the land should be covered thickly with well-rotted manure, and dug in fairly deep. Then leave it until it is time to measure and peg out the rows for the different vegetables. For carrots, make a trench with the hoe, sow the seeds fairly thickly, water them well, and keep all weeds pulled, and carrots thinned out when the small plants have made a good start. Parsnips are best sown 10in. to 12in. apart, with two to three seeds in each place. They can then be pulled up, leaving only one to grow. Cabbages and cauliflowers should be sown in pans or boxes in March, so that they can be planted in April. Always choose a dull day for transplanting, and water every morning and evening to prevent them from getting a check. Plants that have been left in the dishes too long run up to seed very quickly and do not form a nice heart. Drumhead is the best variety; they last quite a long time after they form a heart, if they are covered with leaves to protect them from the sun and damp. Phenomenal Maincrop Cauliflowers are a good variety. They take six to seven months to grow. They should have plenty of water and be kept free from insects and grubs. A little sulphur put in a sugarbag and shaken over them keeps out the grubs and insects. Spraying is necessary to check aphids. Beetroot is best sown in a dish, so that it can be planted out evenly in rows. Crimson Globe is a good sort. Peas should be sown in April; if climbers, a trellis should be provided. Onions must be planted out in April and not given too much water. They are best planted on one of the outside rows. The roots must only be put in the ground, and then as they are growing the soil kept away from the bulb, so that it is above ground. The tops can be bent over when they are about 1½ins. through. Lettuces planted out in the beginning of July and kept watered will grow quickly. Radishes can be sown in August. The ground must be hoed and loosened about every week, and given an occasional good soak in water."

Meeting held November 7th. Present: 15 members and two visitors. Miss Kelly gave a report of the Annual Congress. Miss O'Loughlin gave some useful hints on cooking. (Secretary, Mrs. F. Atze.)

**PARILLA WOMEN'S (Average annual rainfall, 14.15in.).**

September 11th.—Present: 20 members.

**QUESTION BOX.**—The following questions were submitted and answers supplied by various members:—Why does sponge cake go flat when taken out of oven? Reply—Insufficiently cooked or taken out of oven and placed in draught. Correct way of jointing poultry? Reply—Cut off legs and divide each into two portions, then cut off wings, slice breast, and break carcases in two. How to mix correct ingredients for sponge sandwiches? Three eggs, half cup sugar, 4 tablespoonfuls cornflour, 1 tablespoonful plain flour, bare teaspoonful cream tartar,  $\frac{1}{2}$  teaspoonful carbonate soda. Beat eggs until frothy, then add sugar, and continue beating until thick and frothy (about 20 minutes). Sift cornflour, flour, and mixing together two or three times, then add all to egg mixture and stir lightly until well mixed. Bake in fairly hot oven. How to bake a good egg custard? Reply—Beat 2 eggs into a pint of milk, adding a little sugar and flavoring. Place dish in pan of water if oven is hot or in a moderate oven without water. How to make marble cake? Reply—One cup butter,  $1\frac{1}{2}$  cups sugar, 3 cups self-raising flour, 4 well-beaten eggs, 1 cup milk. Beat butter and sugar to a cream, add eggs well beaten, then milk and flour. Divide into three parts; color one part with cochineal, one part with cocoa, and leave one plain. Drop spoonful of each in dish until all is used. Bake in moderate oven. How to make and bake a sponge roll? Reply—Same recipe as for a sponge cake. To bake, put sheet of brown paper on oven tray, pour sponge mixture on paper, and bake until cooked; turn out, then take a damp cloth and rub over paper, when it can be removed easily from cake; spread with jam and roll quickly. How to feed young ducks? Replies—(a) Feed with hard boiled egg and breadcrumbs for a few days, then mix bran, pollard, and chopped green food with milk or water. (b) Give mash from hatching. What makes butter cheesy? Reply—Keeping cream too long before churning. Best cure for sore teats on cow? Reply—Mix together equal parts vaseline and lard and apply. Best time to hatch turkeys? Reply—August and September. Cause of fruit rising to top of bottle after preserving? Reply—(a) Bringing water to required temperature too quickly; (b) overripe fruit; (c) syrup too sweet.

Meeting held October 16th. Present: 17 members. Delegates' report on Annual Congress was received and discussed.

**TOMATO GROWING.**—The following paper was read by Mrs. Phillis at the meeting held on November 19th, which was attended by 22 members:—“In this district seed should be planted in pots or tins in June and July. If tins are used, holes should be punched in the bottoms of the tins. Cover the holes with charcoal. Fill with rich soil and sprinkle in the seeds, not too thickly. Cover the seeds with sand, place the pots or tins in a heap of stable manure, sloping a little towards the north, and cover with a glass frame. Always keep the soil moist. When the plants are about 1½ins. high take the glass off in the daytime. This makes the plants strong and hardy. Care should be taken to always cover them at night. Prepare the ground, selecting for planting the plants by giving it a heavy dressing of well-rotted stable manure from 2ins. to 1½in. thick and a sprinkle of bonedust, and dig it in about 5ins. deep during August. When ready for planting give it another application of bonedust and dig again. When the plants are ready to transplant, space them 2½ft. apart, in rows 3ft. apart. Cut kerosene tins in halves, leaving two sides and the one end on each, and place one half over each plant. Leave these over until there is no danger of frosts. Water every other day until the plants flower, when a thorough soaking once or twice a week will suffice. Prune the

plants by nipping out the shoots just below a bunch of flowers. When frosts are over, remove the tins, place 4ft. stakes beside each plant, and tie carefully. The following varieties are recommended:—Early Dwarf Red, Early Jewel, Burwood Prize, and Ponderosa." (Secretary, Mrs. Welden.)

#### PARILLA WELL WOMEN'S (Average annual rainfall, 14.94in.).

Meeting held September 30th. Present: 16 members. An interesting report was received from the delegates who attended the Annual Congress. (Secretary, Miss S. Burford.)

In the November, 1930, issue of the *Journal of Agriculture*, page 438, the report under the heading of Parilla Women's should be Parilla Well Women's.—[Editor.]

#### PARRAKEE WOMEN'S (Average annual rainfall, 14.54in.).

November 24th.—Present: 16 members and 23 visitors.

Mr. F. C. Richards (Assistant Secretary of the Agricultural Bureau) addressed the meeting. Mrs. Pritchard, of the Wilkawatt Branch, reported on the Adelaide Congress. (Secretary, Mrs. M. Cabot.)

#### TAPLAN.

After having been in recess for some months, an excellent meeting of the Branch was held on August 20th, there being present Mr. W. Hammond (Chair) and 12 members. Officers for the ensuing year were elected (Secretary, Mr. P. Hodge, Nangari.)

#### WILKAWATT WOMEN'S (Average annual rainfall, 16in. to 17in.).

Meeting held October 30th. Present: 10 members. The report of the delegates who represented the Branch at the Annual Congress was received and discussed. (Secretary, Mrs. A. Oram.)

### SOUTH AND HILLS DISTRICT.

#### BLACKWOOD (Average annual rainfall, 27in. to 29in.).

September 8th.

Mr. F. James presided over an attendance of 11 members. Mr. G. Summers addressed the meeting on the subject, "The Root Growth of Trees after Receiving an Application of Sulphate of Ammonia." (Secretary, Mr. R. Quinn.)

#### GUMERACHA (Average annual rainfall, 33.54in.).

The meeting held on September 1st, which was attended by 12 members and two visitors, took the form of a debate on the subject, "Bores v. Dams." Mr. H. Hanna spoke in favor of bores and Mr. V. Lee supported the advantages of dams. An interesting discussion followed. (Secretary, Mr. L. Wise.)

#### INMAN VALLEY (Average annual rainfall, 26in. to 27in.).

August 21st.—Present: seven members and four visitors.

**ERECTION OF THE HOMESTEAD AND OUTBUILDINGS.**—The following paper was read by Mr. W. Mayfield:—"The first consideration should be the site and the layout of the various buildings. Buildings are put up to remain for a good number of years, and it is well worth while considering selecting the best site possible. The following points are well worth considering when selecting the position of the homestead:—1. As central as possible, but not overlooking the necessity for easy access to the main road. 2. On rising ground to ensure a fall for drainage waters. 3. Gravelly ground is the best to build on; it ensures dry and clean surroundings during winter months; failing this, sand is next. 4. Water supply from higher ground if possible. 5. Place the homestead in front and the other buildings at the rear, as sometimes it is to the reverse. 6. *Cost of Construction.*—This is a matter of discretion. I maintain that the average farmer must build a home in accordance with his natural income. By this I mean it is no good in building an elaborate home on a small holding which has not the producing qualification in paving the way for its inhabitants. After having made your plans, and having the lay-out of your homestead, one can then endeavor to commence with the construction. That is, providing you have the stone carted and put in a symmetrical shape from where the structure is to be erected. I have unanimously decided on a stone building as the surroundings are adapted to good building stone. But where stone is scarce, as it is in some districts, it is a debatable question whether stone buildings are preferable to iron ones. The foundation should be concreted with a damp-proof course, preventing the dampness rising up through the walls. These two points have only come into vogue of recent years, but no doubt they will remain, as they both aid the life of the

# THE IMPLEMENT CO.

Offer a Complete Line of

## Harvesting Machinery

Don't risk a whole year's work when you can ensure against loss by getting light running, easily handled harvesting machinery on which you can always depend to harvest and market your crop. You will find in the Implement Co. line the finest materials and workmanship—and, what's best of all, years of satisfactory service.

**HORWOOD-BAGSHAW  
"GASTON" HEADER.**

The simplest, easiest running, and most effective Reaper Thresher in Australia. Sizes, 8ft. and 10ft. cut. This machine has fully earned its name—"The Better Built Header."

**HORWOOD-BAGSHAW  
"ILLMAN" STRIPPER.**

The Horwood-Bagshaw "Illman" Stripper is the result of many years close attention to the requirements of Mallee Farmers, and we are confident in offering this machine to fill the demands of the most exacting user. Made in 8-ft., 9-ft., and 10-ft. sizes.

~~~~~  
Write for catalogs and prices of the above, also "Horwood-Bagshaw" Winnowers, "Austral" Binders, "Horwood-Bagshaw" Wheat Elevators, "Frost & Wood" Hay Rakes and Hay Balers.

**BANK AND BLYTH STREETS, ADELAIDE.**

building. I suggest having a six-roomed house, with a verandah at all sides, which keeps the effects of the sun and rain from the walls. A laundry and bathroom can be made by enclosing the back verandah in, which are both essential to an up-to-date home. The kitchen should be a moderately large room, thus giving the women folk more freedom. This is the most used room in the home, so the most attention must be given to make it as convenient and as comfortable as possible. No home is up to date if it is lacking in way of convenience. By having the water laid on from the higher ground into the kitchen it gives the household folk a good deal of extra time. Every possible effort should be considered, in the way of making work a pleasure, whereas if no convenience, one has a lifelong burden. *The Site of the Home.*—The front should face east or north, having the back portion screened off by the outbuildings, and trees cutting out the south and west winds from which our district suffers generally. The outbuildings should be screened off from the homestead, excepting the motor garage, preferably by a plantation of trees or a hedge. Avoid erecting buildings in such a manner that the prevailing winds blow straight from the farmyard to the house. As far as possible keep the general layout of the buildings in a rough quadrangle. The buildings should be placed so that those most used are nearest the house, probably in this order:—Car or buggy shed, workshop, fowls, pigs, cowshed, stables, and shearing-shed. The surroundings to these buildings should be kept as clean as possible. Do everything to avoid a boghole in the winter. The first building, namely, the motor garage, should be built with stone; as it is the nearest building to your dwelling, why not keep it up to the same standard. The measurements which I think most suitable, 18ft. x 10ft. clear space, giving yourself plenty of room for minor repairs; also a pit is very serviceable, as it enables one to do his jobs more easily. This can be concreted with 3in. thickness of the walls and the floor 2in., which prevents the water from soaking in; if not treated in such a manner it will be very little use. The second building I have considered to be the next most used should be built by the man on the farm; not necessarily to be as elaborate as the garage. This could be built with timber and iron, but do not overlook the fact in making it too small. If it is a solid construction, and its contents are plentiful in the way of carpenter's tools, one will occupy a lot of his time in this building, especially in the winter time. *The Fowl, Pig, and Cow Sheds.*—These can all be built by the owner if he is studying finance, and a very satisfactory job can be done. They all will show a profit if built in an up-to-date fashion. As we all know, if animals are taken greater care of they will return a bigger profit, so why not give all the attention in making this building as up to date and as comfortable as possible. In building the fowlhouse I advocate an iron roof, closed in with iron on three sides, leaving the front exposed to the east. The perches should be old pipes, as these leave no harbor for vermin. A netting yard surrounding the house will enable them to have the required amount of liberty. The pigsty should be built of stone, with concrete floors, with a gradual slant to the middle, thus enabling all liquid matter to be cleared. *The Cowshed and Stable.*—These two buildings would be better built of timber and iron. The former could be made to house three or four cows. These, cared for properly, would produce more than the unhoused ones; each having its own stall and feedbox, with a vacancy at the front to enable one to feed more easily than coming up from the rear. The stable could be similarly built, having an extended shed at the end where food could be stored, such as chaff and hay and such like. The last building I have chosen is the shearing-shed, as it is used only once a year to any extent, but can be used for storage of super and miscellaneous articles. The measurements for this building I have chosen from William Cooper's Note Book:—Length 40ft. x 30ft., which is the required size for the average grazier. It is advisable to build off the ground, which gives you another sheltering quarter under the shearing board. By having the building off the ground one has to overcome the difficulty in penning the sheep. This can be overcome to some extent by the use of a ramp leading up to the entrance-door by a gradual slant. The ramp can be made of the same material as the grating. These measurements are 1½in. x 1in., leaving a space of three-quarters of an inch for clearance of rubbish. The entrance-door should be made to slide. This can apply to all doors and gates within the building, as it is less trouble than closing a gate in a crowded yard. The sheep having entered the shed, should be raced off on either side, where the yard on the left can be used as a holding-pen and the one on the right can be used as catching pens. This plan gives ample room for four shearers, allowing two shearers for each pen, so the catching pens can be divided into two compartments, each measuring 9ft. x 12ft. The shearing board should be at least 9ft. wide, to enable the woolpicker to walk along at the back without interfering with the shearer. Each shearer should have a porthole for disposal of his sheep, entering into a small private yard, which would be most beneficial for employee as well as employer. The remaining area, 12ft. x 30ft., would be utilised for rolling and storage, with another sliding door for the exit at the opposite end from entrance."

**FENCES.**—Mr. E. B. Stone read the following paper:—"One of the first moves to make on securing a farm or grazing property is to put the fences in order, especially the ring fence. Good fences add to the attractiveness of a farm, and such will, if in case of sale, greatly help in securing the full value of such. To have good fences in almost every case you will have good and friendly neighbors, for most of the troubles between neighbors start with stock trespassing, all through fences being out of order. One of the most important items in erecting a new fence is to secure good pink gum split posts, 5ft. 8in. long and 4in. to 5in. across the top, and strainer posts 7ft. long and 12in. across the top. The pink or sand-gum is by far the superior timber for durability, with the red and blue next. Red gum timber does not last too well in the ground, and the blue gum timber is very subject to white ants. In erecting the fence, have not less than seven posts to the chain, and for the ring fence not under 3ft. 10in. high; a division fence need not be quite so high. I consider a seven-wire fence very superior to a six for a boundary fence, but six wires are quite sufficient for subdivision. It is far better to pay the extra cost and secure all galvanized wire, as the black rusts out so soon, No. 10 galvanized being superior to the No. 8 black. In fencing against horses and cattle, No. 8 wire is small enough for the three top wires. I also prefer to have one barb on top of the posts, or the second wire down, to protect the fence, the second one being my favor, tied with galvanized wire, not staples, or tied with old rusty wire, as it rusts the barb. Also, to have the fence effective, the wires must be strained well, and also kept tight, with each strain from 8 to 10 chains long. I do not consider the cyclone fence as good as the one I have stated, especially for the ring fence; if it is it will have to last for 60 years or more. I have just pulled down a seven-wire ring fence, erected 50 years ago, and it would have lasted another 10 years for some farmers. The 12½ gauge high-tension wire goes a long way, but that is the only point in its favor so far as I have proved. In this district where posts are almost unsaleable the dropper fence needs little comment, as it cannot compare with posts for strength when tested with heavy stock. Another important item is to have good gates, for then you can get from one paddock to another without delay, and I am a great advocate for the cyclone iron gate, in preference to wood, which are quite as cheap and last longer."

**MOUNT PLEASANT** (Average annual rainfall, 27-38in.).

August 8th.—Present: 11 members.

**FARM MANAGEMENT.**—In the course of a paper under the title, "Adversity on the Farm," Mr. D. Learmonth said perhaps the most trying circumstance, and one which was beyond the control of the farmer, was the occurrence of a drought. When the farmer had reduced the stock on the holding to a minimum and the rain still held off, and he was without capital to purchase fodder which suddenly jumped to very high prices, it was very distressing to know that one could do nothing for the stock. Despite these happenings, which had been experienced by many men on the land, he doubted very much whether producers had yet learned any lessons from the drought. Reserves of fodder were an absolute essential to the proper conduct of the holding, and the time to make adequate provision was during seasons of plenty. "Cut an extra stack of hay, and see that precautions are taken to prevent damage to it by mice and rats." Farmers should not overlook the value of a stack of good oaten straw. This chaffed, and an allowance of oats added, would do much towards keeping the stock alive. He thought the harvester had been responsible for the comparatively small amount of cocky chaff that was saved. It would prove a valuable asset in times of drought. A good stone wall about 4ft. high would considerably reduce the fire risks so far as the fodder supplies were concerned. Care should be taken not to let the stock get too low in condition before starting to hand feed them. Breeding ewes should not be too fat at the time of lambing. A good plan was to feed them on grass hay with a small quantity of bran, shift them directly they had lambed and give an oat ration. Any weak ewes should receive special attention when hand feeding was started, otherwise they would not get their fair share of the fodder. They could be placed in a small paddock and, if necessary, the lambs given a little milk for a day or two. The provision of shelter in the lambing paddock was an important point in the management of the flock. It was not profitable to feed old or useless stock in times of scarcity. Rabbits on the property should be kept down; they ate much valuable grass which should be utilised by the stock. Mr. Learmonth spoke very strongly against the losses caused by foxes, and urged every landholder to use every effort to destroy them. The blowfly was also responsible for considerable losses to the flock master, and much would be done to minimise trouble if all carcasses were either buried or burnt. The speaker also referred to the loss of grass that followed as a result of cropping, and in districts where the rainfall was sufficient it might be advisable to sow grass seeds immediately the crop had been taken off. Practically every summer there was the menace of fire to be faced by the landholders in the hills districts, and every possible precaution and action should be adopted to minimise danger and loss from this cause. (Secretary, Mr. D. Smith.)

# CROWN LANDS.

## LIST OF LANDS OPEN.

The attention of intending applicants for land is directed to the Official List of Lands Open which is published half-yearly (in January and July). The list shows the areas, localities, prices, short general descriptions, &c., of the sections available, and the conditions under which they may be applied for.

Copies of the list may be obtained on application to the Director of Lands, Adelaide.

## APPLICATIONS FOR LAND.

Intending applicants for any lands which are open for application are reminded that application may be made for the whole or any portion of a block. The Land Board has power to allot portions of a block if considered advisable, and to adjust the purchase-money or rent. If only portion of a block is applied for, deposit of a proportionate amount must be made, and the successful applicant would be required to pay cost of survey of the subdivision.

## ADVANCES TO SETTLERS.

The administration of the various Acts dealing with advances to settlers has been committed to the State Bank of South Australia by the State Bank Act, 1925. All applications should be made to the Chairman, Board of Management, State Bank, Pirie Street, Adelaide.

R. S. RICHARDS, Commissioner of Crown Lands.

## AGRICULTURAL VIEWS AND COMMENTS.

### Agricultural Bureau Conferences.

District Conferences of Branches of the Agricultural Bureau are being arranged as follows:—

Lower North, at Lyndoch (Secretary, Mr. J. S. Hammat, Williamstown), February 26th.

Mid-North, at Wirrabara (Secretary, Mr. F. E. Borgas), March 11th.

South-East, at Kalangadoo (Secretary, Mr. J. Dignan), March 18th.

The above Conferences will commence at 10.30 a.m. in each case. Arrangements are being made for special sessions for members of Women's Branches. Papers and questions for Conferences should be sent to the General Secretary, Agricultural Bureau, about a fortnight prior to the respective dates mentioned.

### Should Crops be Sown Without Superphosphate This Year?

"In view of the low price offering for wheat, and the difficulty of financing the purchase of manure, would it be wise to sow the wheat crop without superphosphate this year?"

In reply to this question, Mr. W. J. Spafford, Deputy Director of Agriculture, stated that even though some of our wheat lands had been regularly manured with superphosphate for a long time now, it was still necessary to use this fertiliser with the wheat crops, if profits were to be secured. The improved methods of soil cultivation which had been developed in recent years enabled us to grow much heavier crops than was possible a few years ago, and when good seasons return it was anticipated that high-yielding crops would be common in all of our better wheat-growing districts. Nevertheless, cultivation alone, no matter how thorough it might be, would not be sufficient to secure big crops. Fortunately, a good deal of field experimental work had been carried out in connection with this question of the value of Superphosphate for wheat crops, and the following figures were the averages of the results secured at 17 wheat-growing districts in South Australia, the period being up to the 1928-29 crop, and varying from one season at Cortlinye, Coorabie, and Copeville to 22 at Roseworthy Agricultural College, the total number of experimental series harvested during the period being 112:—

\* Superphosphate valued at 5s. per cwt.

These figures show that even at the extremely low prices of 2s. and 2s. 6d. per bushel for wheat the application of up to 1cwt. of Superphosphate per acre was a highly remunerative business proposition.

Without Superphosphate, Mr. Spafford added, it was impossible to produce full wheat crops in South Australia, and all those who could possibly finance it should continue the practice, even though a lesser amount be used than was the case when prices for wheat were higher than they promise to be in the near future.

**Botulism in Horses.**

A case of botulism in horses, assumed to be caused by feeding on ensilage, was recently investigated by veterinary officers of the Stock and Brands Department. Five horses had been accidentally given access to ensilage which was about 18 months old, and on the following day one died, followed by the deaths of the remaining four a week later. The ensilage had apparently caused the deaths of rabbits and hares, but not of sheep which had been fed similarly.

The owner of the horses stated that the silage appeared to be of good quality and free from mould. It had been made in pits and a very heavy weight of earth placed upon it. When the pit was opened the top layer had been removed and not fed to any stock. The symptoms of the affected horses were paralysis of the tongue in some cases, and others were down and could not get up.

Although it was known that another farmer fed his horses on silage from a pit silo (with earth sides) at the rate of about 12lbs. per day during the summer months without noting any ill effects, the veterinary officers were of opinion that owing to the danger of ensilage in the making being liable to damage by fermentation, mould, &c., on broad principles it was not advisable to recommend it as a food for horses, which were not so tolerant to damaged fodder as sheep and cattle. In commenting on the reason why the ensilage became infected with the *bacilli* which causes botulism, Dr. Lionel B. Bull (Director, Laboratory, Adelaide Hospital) stated that while the *bacilli* was an inhabitant of the soil it was not at all likely that ensilage in pits would more commonly become infected than that in concrete silos, as the plant itself probably contained the spores (on surface of leaves) before being placed in the pit. Although it was possible that the *bacilli* might grow out from the sides of the pit into the ensilage, for the most part the sides of the pit would be below the area of maximum bacterial growth in the soil. The frequency of occurrence of botulism in horses fed on hay recently cut from stacks was sufficient to indicate that the growth of the *bacilli* might occur under conditions far removed from those found in pit silos. It was not certain, although it seemed probable, that ensilage was more frequently infected with the *bacilli* than other stored forage. More care in feeding ensilage to stock might be observed, and where horses, particularly, had to be fed the ensilage should be exposed to the air for three or four days before it was used. Where the greatest care was necessary the ensilage could be sprayed with chlorine water made from bleaching powder and left exposed for 48 hours to allow the chlorine to escape and oxidation of the toxin to occur.

**Demand for Empire Butter.**

The Trades Commissioner, in a report dated December 17th, 1930, writes as follows:—"The following extracts are from a report entitled 'The Demand for Empire Butter' recently issued by the Empire Marketing Board:—Imports of butter into the United Kingdom during 1929 totalled 6,500,000cwts., or, in terms of boxes, 13,000,000 boxes. Home supplies based on latest figures available were approximately less than 1,000,000cwts. The largest exporter to this country was Denmark, who supplied 34 per cent. of the total import; New Zealand supplies were 20 per cent.; Australian, 12 per cent.; Irish Free State, 9 per cent.; Argentine, 5 per cent.; other foreign countries, 19 per cent. The main channels through which butter is imported into the United Kingdom are:—Australian—Mainly through London, with smaller quantities passing through Liverpool and Glasgow markets. New Zealand—Mainly through London, with Glasgow, Liverpool, and Bristol handling smaller supplies. Irish—Through ports on West Coast. Danish—Imported through ports on the East Coast. Russian, Argentine, and other European—London, Southampton, Hull, Newcastle, and Edinburgh. The report states that the most notable development in the import trade was the rapid

expansion of exports to his country from New Zealand. Australian supplies have also increased considerably; and South Africa, too, has begun to export, 12,000cwts. being received in 1929; but Canada has ceased to export butter to this country. Imports during 1929 were nearly 2,250,000cwts. above the average for the years 1909 to 1913, and, of this increase, 75 per cent. was accounted for by Empire butters and nearly 50 per cent. by New Zealand imports. The seasonal nature of the trade is emphasised by the fact that although supplies from Australia, New Zealand, Irish Free States, and Denmark are received throughout the year, in 1929 Australian supplies were heaviest during the months December-May; New Zealand, November-June; Irish Free States, June-October; while supplies from Denmark were fairly even throughout the year. The inquiry was made in two parts, late spring and during the summer months, and nearly 3,000 retail traders in 18 towns were interviewed. The result of the first survey (April-June) showed that Danish butter was stocked by 58 per cent. of the shops, and in the second survey (July-September) by 59 per cent. New Zealand, 35 per cent. in the first survey, but dropping to 28 per cent. in the second. Australian in the first survey was stocked by 10 per cent., but dropped to 3 per cent. in the second survey. Irish jumped from 12 per cent. in the first to 22 per cent. in the second survey. Argentine showed 4 per cent. in both surveys. Bulk blended butters, 9 per cent. in each survey; and packed butter, 32 per cent. in the first and 31 per cent. in the second survey. New Zealand butter, it is reported, was most frequently stocked in the south and early in the year in Liverpool. In Yorkshire and Scotland it was fairly frequent in non-local multiples, but rare in other shops. Australian butter was most popular in London and Birmingham, but rarely stocked in the north and east. It was most frequently found in non-local multiple shops and in co-operative stores. The main market for Irish was in the west, and it was also stocked in London and Glasgow. The staple butter in the north and east was Danish, and in Liverpool and Birmingham the demand was about the same as for Empire butters, but in London, Bristol, and South Wales it was much less commonly found. Argentine was chiefly stocked in London and Birmingham; Siberian in Birmingham and Bristol; Swedish and Finnish in the north; Ukrainian was stocked by one large multiple firm in all parts of the country; Dutch and French mainly stocked in London. Packet butters under a brand name were the staple type in dairies, and were stocked by about 30 per cent. of the grocers in addition. This type was most popular in London and Edinburgh.

#### **Publications Received.**

"Australian Dairyman's Handbook."—Published by Mr. Ralph S. Maynard, of Queensland. The "Australian Dairyman's Handbook," says Mr. H. B. Barlow (Chief Dairy Instructor) fills a long felt want for those engaged in the dairying industry in Australia. It is the most complete manual on dairying that has been published for Australian conditions. The subject matter on the management of dairy cows, including the feeding of stock and growing of crops, is all that could be desired. The importance of pigs as an adjunct to dairy farming has not been overlooked, and this aspect of the industry has not received the consideration in the past to which it is entitled. A feature of the book is the excellent numerous illustrations. These include examples of the various breeds which can be used as ideal types for dairymen throughout Australia. Undoubtedly this book should be in the hands of all dairymen who have the welfare of the industry at heart. Mr. Maynard has presented an ideal which every dairyman should strive to attain. The book is priced £2 5s., and can be obtained from Messrs. Angus and Robertson, Sydney, New South Wales, and local booksellers.

# The Fordson's Outstanding Performance

**THAT** the new Fordson Tractor will do an eight-horse job—and more—in half the time and at a fraction the cost of horses, is being proved by progressive farmers all over Australia. And never were time and money more valuable than in these days of insistent clamour to “reduce farm production costs.”

The following extracts from letters recently received from owners of the New Fordson are surely proof enough of Fordson superiority over horse-team work.

*“Using a fifteen-hoe I.H.C. Combine we have ‘combined’ 130 acres with a kerosene consumption of 2½ acres to the gallon. Using a 10-disc Sundercut in fair ground we worked 50 acres on 32 gallons of kerosene. On these operations the throttle was opened only one third, yet the work would be a 9-horse job. The oil consumption is one quart per day.”*

**AGRICULTURAL INQUIRIES.**

---

[Reply by Prof. A. J. PERKINS, Director of Agriculture.]

---

**Ensilage.**

"R. G.," Swan Reach, asks—(1) Is it necessary to "mason" the sides of a pit silo? (2) Must the silo be kept airtight? (3) Can green lucerne be carted into the silo? (4) Can one mix with lucerne silver beet, barley, oats, &c., and yet make good ensilage? Replies (1) If the soil is of a stiff clay nature there is no reason why it should not prove suitable for an ensilage pit. The only difficulty is, however, that to get the best results out of ensilage there ought to be a definite relationship between the diameter of the pit and its height, thus, roughly speaking, a 100-ton ensilage pit should be about 30ft. high, with a diameter of 15ft.; a 50-ton 24ft. high, with a diameter of 12ft. In the circumstances it would probably be difficult to get a sufficient depth of suitable soil for your purpose.

(2) When the pit is being filled up one should aim at making it airtight as much as possible on the sides by tramping the green material down near the sides. The main advantage of this is that if air gets between the wall and the ensilage the outer edges are apt to become mouldy, and when subsequently the ensilage is fed to cattle the mouldy portions, unless carefully separated, would lead to digestive troubles and other disadvantages. The same applies to the top of the pit. The top of the pit will tend to become mouldy if left exposed to the air for any length of time. That is why, when taking out ensilage from a pit, it is advisable to take as shallow a layer as possible so as to remove the whole of the surface in one day.

(3) Do not allow the green material intended for ensilage to dry out to any extent. In other words, do not cut more greenstuff than you can cart in the same day. Otherwise there may be difficulty in getting a suitable rising temperature, and the ensilage will not pack well.

(4) Any good mixture may be made for ensilage purposes. As a matter of fact, lucerne alone does not make the best ensilage, and it is preferable to associate with it green barley, oats, &c.

---

[Replies by Mr. W. J. SPAFFORD, Deputy Director of Agriculture.]

---

**Lucerne Growing.**

From a correspondent at Coomandook. (1) What would be a fair yield per acre from a fairly good stand of lucerne on Jervois (River Murray)? Reply—The yield of seed of the lucerne crop is probably more affected by the weather than almost any other of our cultivated crops, and this is so much so that one decent rain will often convert a promising seed crop into a poor hay crop. Given good weather, however, a fair yield of seed would be about 200lbs. to 300lbs. per acre; in some conditions more could be expected, but the yield would then be looked upon as a good one. (2) Owing to the presence of water within 2ft. or 3ft. of the surface, will the seed mature properly on the swamp when plants are left for seed. Reply—The presence of the underground water so near the surface is not an advantage for seed production, as it will lead to too much growth, but if no rain falls during the development of the crop its effect is most likely to be delayed ripening and difficulty in harvesting because of the luxuriance of the growth. (3) The plot was planted in August and all of it has been cut once and some of it twice. Can it be cut, say, twice more and then left for seed, or when is the best time to allow it to go to seed and when should it be harvested? Reply—Seed is usually taken from older stands of lucerne, but if weather

conditions remain favorable you may get a crop from this young stand. There is no chance of getting seed, however, if another hay cut is taken, because there will not be time for the seed to mature properly before the cold weather comes. The seed would be harvested during March. (4) After harvesting for seed, would the plant be destroyed or will it shoot from the roots again? Reply—The production of a crop of seed does not injure the stand nor the individual plants in any way. (5) What machinery is generally used for harvesting lucerne seed? Reply—In the north of the State, where so much good seed is collected, reaper-threshers with specially constructed fronts are used to harvest the seed direct, or strippers collect the pods and the unthreshed ones are repeatedly passed through the drum of a stripper being pulled along or blocked up and driven by an engine. In the latter case the cleaning is done with an ordinary winnower.

#### Sheep Grazing off Cape Barley and Oats.

“F. H. B.,” Paskeville, reports that he has a 70-acre field sown with Cape barley and oats. Although this has been fed down continuously there still remains a considerable quantity of surplus feed which presents a rather difficult problem. The crop should yield 6 bush. to 8 bush. to the acre. Would it be safe to allow a flock of ewes and wethers to graze off the crop. Reply—No difficulty should be experienced with the animals in a mixed flock of sheep from the grain still left on the crop, provided that some time is permitted the sheep to become used to the feed. The first day that the flock is turned into the field, the sheep should be full and should not be allowed to remain for more than an hour or so. The next day the time can be extended and so on each day for five or six days before leaving the flock full time.

#### Mustard (Charlock) as a Commercial Proposition.

“F. H. M.,” reports that he has 100lbs. of mustard (charlock) seed for sale and asks if it is of any commercial value. Reply—The department has no record of anyone growing either hedge mustard (*Sisymbrium officinale*) or wild mustard (*Sisymbrium orientale*). Although the plants are sometimes eaten by farm livestock they cannot be looked upon as good feed, and so can hardly be recommended for this purpose, particularly as they are such troublesome weeds where cereal crops are grown.

#### Fertilisation of the Wheat Plant.

At what stage in the formation of a wheat plant do the grains likely to mature actually set? (Blackheath Branch.) Reply—The organs of reproduction of the wheat plant consisted of:—(a) An ovary (that eventually developed into a grain), on the top of which were two feather-like appendages known as stigmas, as the female organs; (b) three pollen sacs, known as anthers, as the male organs. These female and male organs were enclosed between two scales or glumes, usually known by farmers as the chaff, and the whole was known as a floret. Three to five of those florets were grouped together and were known as spikelet. Several spikelets were fixed alternatively on opposite sides of a stalk, to form what was known as a head or ear of wheat. As soon as the floret of a wheat head had flowered, i.e., as soon as the pollen had matured and been scattered over the feathery stigmas at the top of the ovary, fertilisation of the ovary took place, or, in other words, the grain had “set.” If favorable conditions followed fertilisation, all ovaries fertilised would develop into grains, but if extreme changes in the weather occurred, or diseases such as “take-all” or “red rust” were present, some of the fertilised ovaries might not develop properly.

#### Red Rust in Wheat.

What is the cause of red rust in wheat and its effect on grain? (Blackheath Branch.) Reply—Red rust is a fungus which lives on the wheat plant and obtains all its sustenance from its host. The reddish powder found on the surface of the leaves and

sheaths, if examined under a microscope, will be seen to consist more or less of oval cells on short stalks. When weather conditions are favorable, i.e., "muggy" weather, the spores germinate by sending out thin threads which enter the breathing spores, grow into the wheat plant, and reproduce themselves by thousands in a few days. This very rapid multiplication of the rust plants eventually leads to the killing of the affected wheat plant, because the sap which should have travelled to the wheat heads to develop the grain is all intercepted by the rust plants. In mild attacks, the grain is usually "pinched" because insufficient sap reaches the heads to allow of full development, but in severe attacks, when the spores reproduce themselves by thousands every few days, the parasite uses all of the sap of the host plants.

#### **Best Time to Work Fallow.**

What is the best time to work fallow? (Palabie Branch). Reply—The correct time to work fallowed land varies with the soil texture. Heavy textured land which sets readily should be ploughed about 3in. deep, allowed to stand throughout the winter, receive its first cultivation in the early spring (usually in September in this State), and be cultivated or harrowed every time sufficient rain falls to form a crust on the surface and when weeds that sheep will not eat are in evidence. Light textured land, such as sandy loams and soils very rich in lime, should be ploughed or cultivated to a depth of 2in. to 3in. early in the season, say, before the end of July, and be harrowed immediately, and, as with other soils, cultivated or harrowed every time that a crust forms on the surface and when weeds that sheep will not eat are in evidence. Sandy soils should only be worked back soon after a rain when sufficiently moist to hold together, and even then the surface should be left as rough as possible.

---

[Replies by Mr. R. C. SCOTT, Supervisor of Experimental Work.]

---

#### **Pacey's Rye Grass.**

From time to time reports have been received regarding a rye grass known as Pacey's, which has been planted in certain areas in this State. It is therefore of interest to publish the following reference made by C. V. Piper in his book, "Forage Plants and their Culture." Dealing with rye grass varieties, he says:—"Apparently this grass is little subject to cross-pollination, and hence varieties are not difficult to maintain. Sinclair in 1825 mentions six different named varieties in England, and intimates that others were known to him. At the present time English seedsmen advertise several varieties of rye grass, but in some instances these 'varieties' are merely seeds of different weights or sizes separated by machinery. The seed is recleaned and graded according to weight and size. The small seeds are sold as short-seeded rye grass or sometimes as Pacey's Rye Grass." From the above it would appear that seed being sold under this name as a distinct variety, and for which special advantages are claimed, is simply a grade of seed separated from Perennial or English Rye Grass.

#### **Tobacco Cultivation.**

For growing tobacco—(1) What type of soil is necessary? (2) At what time of the year does it grow? (3) What rainfall is needed? (4) Where may plants or seeds be obtained? (5) What is the highest production in Australia? ("L. C. B.," Wurrulla.) Replies—(1) Tobacco grows in a great variety of soils, but for the production of the bright leaf required to-day, and which commands the highest prices, a sand overlying a good clay at a depth of from 9in. to 1ft. is essential. All tobacco land must be well drained. Heavier, more fertile soils produce more leaf, but as it is of a coarser texture the price is correspondingly lower. (2) In South Australia the seed is planted in seed beds during September or early October. In about two months' time the seed-

lings are ready for putting out in the field. The transplanting season is, therefore, November and December. With normal summer weather the leaves would be ready for harvesting in March or April. (3) For leaf of the best quality, the soil should be kept moist during the growing period of the crop. A wet soil injures quality and causes sickly growth. Therefore, whilst exceptionally high summer rainfall is not required, the amount which does fall should be regularly distributed. The chief tobacco growing countries receive at least an inch per week, and in well drained situations considerably more. In no place in South Australia have we adequate summer rainfall for maximum returns, and frequently it is not well distributed. (4) Seed is procurable from the Department at a price of approximately 4s. per ounce. With good germination an ounce of seed will supply plants for about six to seven acres. At times growers have a surplus of plants which can be purchased at a charge of about £1 per thousand. No growers are dealing entirely in seedlings, and their availability depends entirely upon circumstances. (5) No figures are available regarding the maximum yield in Australia. In any case, heavy yielding tobacco is of coarser texture and poorer quality. In a general way light soils producing fine textured leaf of maximum value per pound yield up to about 900lbs. of cured leaf per acre. Richer land growing heavier pipe leaf is capable of yielding up to 1,500lbs. cured leaf per acre.

---

### DAIRYING INQUIRIES.

---

[Reply supplied by MR. H. B. BARLOW, Chief Dairy Instructor].

---

#### Food for Dairy Cows.

In a recent communication on the use of concentrates—especially those rich in protein—as an adjunct to the food for dairy cows, Mr. H. B. Barlow (Chief Dairy Instructor) stated that the dairy division of the Department of Agriculture, in conformity with all similar departments throughout the world, was continually advocating the use of concentrates to obtain the best results from dairy cows. Officers were always strongly urging dairy farmers to consider the economic value of supplementing the cow's diet, during the season when rich succulent pastures were not available, with some food or foods of high protein value, to enable the cows to maintain their production. Since most of our locally grown concentrates (cereal, grains, &c.) contained rather a high percentage of carbo-hydrates, the addition of a foodstuff with higher protein content to balance the ration would definitely have a beneficial effect. He was quite certain that any dairyman who fed well-balanced concentrates to his cows could confidently expect much improved returns, and if the feeding was carried out systematically and intelligently the results should prove highly economical.

---

### VETERINARY INQUIRIES.

---

[Replies supplied by Veterinary Officers of the Stock and Brands Department.]

---

“A. I. D.,” Keith, reports cases of lameness in horses, and asks how the seat of the trouble can be located.

Reply—In cases of lameness below the knee, the animal always nods the head, in moving the dipping of the head synchronising with the time the weight is put on the lame foot. If nodding occurs, the affected leg should be carefully examined by passing

the hand down the back of the leg from the knee downwards and applying a firm pressure to the tendon sheathes. In this way any swelling, heat, or pain can be established. The foot should be picked up and searched for presence of nails, stakes, etc., and hoof tested by applying pressure with a wide pair of pincers to the junction of hoof and sole, commencing at one heel and working round the hoof to the other heel, and completely tapping the sole with a hammer. If animal flinches when pressure is applied by pincers or hammer, the spot should be searched for cracks by using a rasp or hoof knife and any cracks followed through to the bottom. In the case of hind limb lameness, the animal will drop on the affected leg when weight is put on it, and same procedure for determining the seat of the trouble as given for examining fore limbs should be applied. The common causes of lameness are strain of tendons and their sheathes, strain of suspensory ligament, which is under the tendons, ricks and sprains of joints, presence of wounds such as cracked heels, bark wire cuts, and foreign bodies in the sole.

"E. M.," Meribah, reports horses troubled with water stoppage. *Post mortem* of the animal showed intestines twisted and the large cavity filled with blood. Other horses have tucked up appearance and will not move.

Reply—The trouble with the horses is not difficulty in passing water so much as bowel impaction, and it is useless—and possibly may even be harmful—to go on trying to put in to them all sorts of drastic medicines to unnecessarily stimulate the kidneys. If you take the care to see that the animals regularly get liberal supplies of drinking water, you will find that they will soon come free enough again in their "water." Give them each a drench of raw linseed oil, 1½ pints; turpentine, 4 tablespoonfuls; and repeat the drench of oil by itself in 24 hours' time. Supplement these drenches by giving an enema of soapy water night and morning for a few days. Mix this in a spoonful of treacle or honey to make a paste and smear it on their tongues and back teeth so that it sticks there and they have to lick it down. Continue this treatment until you succeed in establishing free action of the bowels. Feed them on wet bran with a little good-quality chaff mixed, and after the bowels are working well again the proportion of chaff can be increased. It is no wonder that the horses you blistered so lavishly are tender and up on their toes. In order to assist in their recovery from the ill-effects of this treatment, bathe the blistered legs daily in some warm antiseptic solution, and after washing, smear on a little lard or oil. Do not apply vaseline, or it will only intensify the effects of the blistering.

"J. C. H.," Springton, reports mare lame and with swelling between front legs and belly.

Reply—Give the following drench:—Raw linseed oil, 1½ pints; turpentine, 4 tablespoonfuls, and supplement by giving enemas of soapy water night and morning. Repeat the drench of oil by itself if necessary in 24 hours' time. Also give one flat teaspoonful of powdered nux vomica on the back of the tongue night and morning. Feed lightly on wet bran and chaff and see that the animal has plenty of water to drink. Subsequently to establishing through this treatment a free action of the bowels, feed on nourishing feed with an allowance of succulent feed in the ration daily if possible, and give one tablespoonful of Fowler's solution of arsenic night and morning in the damped feed for a fortnight. Knock it off for a fortnight and then repeat the course again. Regular massage of the oedematous swelling under the brisket will help to promote its absorption.

"E. W. S.," Wolseley, has cow with lump at the back of the jaw which breaks and discharges and then heals again. Reply—Apply hot fomentos to the swelling to induce it to form a head again. Then when it softens, lance it with a clean, sharp knife at its lower edge to permit of free drainage of pus. Keep the wound open so long as any discharge forms and syringe out the abscess cavity (once or

# Scientific Farming!

Economies are necessary, but to cut the application of super in this years farming effort would be a fatal mistake. .

Science and Economy dictate the liberal use of

## W.M.L. EXTRA HIGH-GRADE SUPER

for it lowers costs by increasing yields.

[NATON]

twice daily) with a little tincture of iodine diluted with two parts of water. The condition is probably just a benign abscess but in view of the possibility that it may be actinomycosis, collect some of the pus (or discharge) into a small sterile bottle and forward same to the Stock and Brands Department, Flinders Street, Adelaide, for examination.

"R. W. C.," Minlaton, asks treatment for cut, caused by rusty galvanized iron, on mare's leg, and (2) cause of and cure for greasy heel. Replies—(1) The following treatment for the wound is advised. Rub the proud flesh all over with a piece of fresh bluestone. Apply a pad of cotton wool and bandage leg *tightly*. A strong calico bandage of a good length is required. Remove the bandage night and morning, *massage* the leg thoroughly, and replace the bandage. (2) The cause of "greasy heel" is obscure. The condition is a chronic inflammation of the skin. Treatment.—Clip the hair from the area and clean part by washing with soap and water containing a little washing soda. Dry thoroughly. Apply a pad of cotton wool soaked in a 5 per cent. solution of zinc chloride, which you will have to get from a chemist. Bandage. Do this daily for three or four days. Subsequently apply the following powder on cotton wool to area of bandage:—Salicylic acid one part, zinc oxide six parts. Further, the horse should be given a tablespoonful of Fowler's solution of arsenic mixed in a small damped feed night and morning for 10 days.

"W. G. A.," Tanunda, has cow, udder hard and swollen, milk lumpy and discolored. Reply—The cow is undoubtedly suffering from *mammitis*, and in view of the fact that the disease is now of some weeks standing, it is very doubtful if a satisfactory recovery can be brought about by treatment. If there be any heat and tenderness in the affected quarter, hot fomentations should be applied three or four times a day for 15 to 20 minutes at a time, each fomenting being followed up by massaging the quarter for two or three minutes, rubbing in some camphorated oil. The affected quarter should be "stripped" right out at frequent intervals, even though at each stripping you only get a small amount of milk. This stripping is most important, and if you can carry it out as often as every hour or two, then so much the better the chances of ultimate recovery. This treatment should be persisted in until the milk returns to normal character. Destroy all diseased milk. Do not attempt any injections into the affected quarter. The cow should also be given a purgative drench of Epsom salts, 1lb.; molasses, 1lb.; ginger, 2ozs.; water, 1 quart at outset of treatment and kept on light laxative diet throughout.

"V. E. W.," Millendilla, asks treatment for dog with mange. Reply—The following treatment is suggested:—Wash area with warm water and a good soap, and remove all scales. Apply zinc oxide ointment daily. Re-wash every fourth day. Put dog on to a light diet and regulate bowels by giving a tablespoonful of liquid paraffin daily. Avoid starchy foods. Give regular exercise.

"E. C. R.," Wepowie, reports death of aged gelding. During lunch hour blood noticed dripping with a gush every five or six minutes; this continued throughout the day. Next morning blood was still dripping with gushes every 15 minutes. The horse then went down and did not rise again. Reply—The case was apparently just one of nasal haemorrhage. This accident may arise from several causes. Most commonly it results from injuries to the nose, but disease of the nasal septum or even severe exertion may give rise to it. Usually the bleeding occurs from one nostril only, though bilateral bleeding is not by any means uncommon and is usually more serious, even being fatal. Treatment consists of keeping the animal quiet with head elevated, but not sufficiently to cause the blood to run to the back of the throat. Cold water should be applied to the head, and the nostrils syringed out gently with cold water, to which tannic acid or vinegar is added. Insufflation of finely powdered alum may be tried where the haemorrhage comes from the lower portions of the nostrils. In severe cases plugging of the nostrils or the injection of adrenalin may be necessary, but these treatments require skilled help.

"W. S. K.," Virginia asks reason for appearance of warts on teats of cow and remedy for same. Reply—Warts are generally believed to be due to some irritation of the skin. Whether this irritation is of bacterial origin or not has not been determined. Some authorities ascribe them to a definite infective origin. They will disappear spontaneously if the teats are kept clean and free from irritating conditions. The rubbing on of castor or olive oil after each milking will often cause them to disappear. The application of salicylic ointment or lunar caustic is also serviceable if the warts are flat. Pedunculated warts can be snipped off at their base with a sharp pair of scissors and the stump touched up with a lunar caustic pencil, but care must be taken to prevent the caustic from getting on to the adjacent healthy skin.

"S. W. S.," Kimba, reports death of horse. Working in reaper, broke out in severe sweat unable to rise off ground. Another horse with the same symptoms died shortly afterwards. Reply—The horses appear to have died from forage poisoning. This ailment is contracted through eating fodder which has become contaminated with the poisonous toxin of the germ known as the *Bacillus botulinus*. It is a disease essentially similar to ptomaine poisoning of human beings. The botulinus germ is a common inhabitant of the soil in many districts throughout the State, and thus it readily gains access to the fodder grown thereon. The germ is not harmful of itself, but under certain conditions favorable to its rapid growth on the fodder it will, while actively growing, produce a powerful poison, or toxin, which is responsible for causing illness and death in horses when taken in by them along with the feed. Do you recollect whether you experienced any showery weather during harvesting so that the sheaves might have been damp when stacked? Treatment of affected animals is not usually hopeful, and, even if they do not die, it is usually some months before they are fit for work again. They should be put in slings (the earlier the better), given a good purgative dose of Epsom salts and a course of powdered nux vomica—one flat teaspoonful three times a day for some days. Feed should consist of bran mash and green fodder.

Crop of Sword (Early Midseason) wheat grown by R. N. Ford and Sons, Windsor. Yield, nine bags per acre; weight per bushel, 63½ lbs. Sown at the rate of 75 lbs. graded seed and 115 lbs. of 45% super per acre.

## SEED FROM CROP COMPETITIONS.

The following competitors in Crop Competitions have exhibited crops which, in the opinion of judges, will produce grain suitable for seed purposes:—

## SHELL PRODUCTS -for the man on the land

CROSS POWER KEROSENE

GOLDEN SHELL OIL

AGRICULTURAL OILS

Each Product is as near perfection for its specific purpose as is possible for modern chemical science to attain. ♦ ♦

### Cross Power Kerosene

The outstanding tractor fuel on the Australian market. Provides maximum power, economy and efficiency.

### Golden Shell Oil

Ensures easier working, and prolongs the life of the tractor.

### Agricultural Oils

As good as Shell Motor Oil. A grade for every type of farm machine.

### Stock-marking Pencils

Three distinctive colours—Red, Blue and Black. Sold in metal containers—do not break or crumble.

### Wool-marking Oils

In four distinctive and fadeless colours—Red, Yellow, Blue and Black. Harmless to wool and skin, and disappear completely in the scour.

### Defiance Blowfly Oil

Prevents blowfly strike in sheep, and has valuable antiseptic and healing properties.

STOCK-MARKING PENCILS

WOOL-MARKING OILS

DEFIANCE BLOWFLY OIL

# NINTH ANNUAL REPORT OF THE TURRETFIELD DEMONSTRATION FARM (1929-30), INCLUDING DE- TAILED ANALYSIS OF MEAN FARMING COSTS (1921-30).

[By ARTHUR J. PERKINS, Director of Agriculture.]

(Continued from page 599).

## WORKING COSTS OF A FAT LAMB FLOCK.

The Turretfield Flock has within recent years consisted of Merino Ewes from which Fat Lambs have been bred by Rams of English Short Wool Breeds. The number of Ewes put to the Rams in each successive season has been as follows:—

|               | Ewes.      |
|---------------|------------|
| 1922-23 ..... | 429        |
| 1923-24 ..... | 458        |
| 1924-25 ..... | 530        |
| 1925-26 ..... | 637        |
| 1926-27 ..... | 683        |
| 1927-28 ..... | 774        |
| 1928-29 ..... | 724        |
| 1929-30 ..... | 678        |
| 1922-30 ..... | <u>614</u> |

The position of opening and closing Inventories for 1929-30 is shown below in contrast with corresponding means for the 1922-29 and 1922-30 periods respectively:—

TABLE XXVI.—*Contrasting 1929-30 Opening and Closing Inventories with corresponding Means for 1922-29 and 1922-30 periods respectively.*

|               | 1929-30 Opening and Closing<br>Inventories. |          | 1922-29 Mean Inventories. |            | 1922-30 Mean Inventories. |           |

| Ewes .....    | 1,024 10 0                                  | 674 0 0  | 871 10 9                  | 968 5 9    | 890 13 1                  | 931 10 0  |
| Hoggets ..... | 175 0 0                                     | 94 10 0  | 60 11 5                   | 81 14 3    | 74 17 6                   | 83 6 3    |
| Rations ..... | —                                           | —        | 11 8 7                    | 10 9 9     | 10 0 0                    | 9 3 6     |
| Totals .....  | 1,243 10 0                                  | 832 10 0 | 990 15 0                  | 1,106 12 7 | 1,022 6 10                | 1,072 7 3 |

It will be noted that the closing Inventory for 1929-30 Season shows a drop in values of £411, and in numbers of 56 only. This difference is due to the general fall in value of Sheep following on the fall in price of Wool. On the opening Inventory aggregate Ewes and Hoggets were valued at 27s. 9d. per head, and on the closing Inventory at 19s. per head. This drop has represented a heavy Loss on the year's transactions. On the eight seasons the Turretfield Flock has averaged, apart from Lambs, 748 head, having a mean value of £1,047 7s. 1d., or 28s. per head.

Flock Mortality for 1929-30 has been shown below in contrast with corresponding means for 1922-29 and 1922-30 periods respectively:—

|              | 1929-30.      |               | 1922-29.      |               | Means, 1922-30. |               |
|--------------|---------------|---------------|---------------|---------------|-----------------|---------------|
|              | Total Losses. | Percent-ages. | Total Losses. | Percent-ages. | Total Losses.   | Percent-ages. |
| Ewes .....   | 50            | 7.4           | 37            | 6.2           | 39              | 6.3           |
| Lambs .....  | 22            | 2.6           | 19            | 4.1           | 20              | 4.0           |
| Rams .....   | —             | —             | 1             | 14.5          | 1               | 13.3          |
| Totals ..... | 72            | 4.7           | 57            | 5.3           | 60              | 5.3           |

Mortality among Ewes, although less than in the preceding season—75 head—continued to be heavy in 1929-30, namely, 50 head, or 7.4 per cent. of the mean total number. The mean total mortality for the eight seasons was represented by 60 head, or 5.3 per cent. of the total Flock, inclusive of Rams and Lambs. Of recent years deaths have been attributable mainly to parturient fever and braxy-like disease.

Flock expenditure for 1929-30 has been analysed below in Table XXVII. for the 1922-29 and 1922-30 Means respectively:—

TABLE XXVII.—*Analysis of 1929-30 Flock Expenditure in comparison with corresponding means for 1922-29 and 1929-30 Periods respectively.*

| 7. Unallotted Expenditure .....      | 163 2 8        | 4 10           | 83 3 11        | 2 9            | 93 3 9          | 3 1            | 11.8       |
| Totals .....                         | 338 1 11       | 10 0           | 196 9 4        | 6 6            | 214 3 4         | 7 0            | 27.1       |
| Grand Totals ..                      | 1,239 7 0      | 36 7           | 727 4 5        | 24 1           | 791 4 9         | 25 10          | 100.0      |

The above Statement shows that on the basis of the Mean Number of Ewes sent to the Rams in eight successive seasons, the mean costs of Handling a Fat Lamb Flock, inclusive of marketing Costs, have aggregated 25s. 10d. per Ewe. In these costs, 4s. 8d., or 18.1 per cent. has been absorbed by Wages; 14s. 2d., or 54.8 per cent. by Feed; and 7s., or 27.1 per cent., by Incidentals. It will be observed that in this statement no account has been taken of Flock Depreciation, which should include progressive depreciation of Breeding Ewes and Rams, and losses from deaths or accidents. This item is included in Inventory differences which appear in the statement of Flock Revenues. In next year's Report it is proposed to split up Inventory Differences, so as to bring out Flock Depreciation.

Under "Feed" four items have been included, namely:—(1) Pasture Grazing; (2) Specially sown Grazing Crops; (3) Foodstuffs; and (4) Water. The value of pasture grazing is determined by the rental value of the land over which the Flock is depastured, plus whatever improvements—such as top-dressing—that may have been carried out during the season. The value of specially sown grazing crops is determined by actual costs incurred in putting the crops in, inclusive of the rental value of the land. When Live Stock other than Sheep are admitted to pastures or grazing crops, their relative shares are apportioned on the basis of one Horse being equivalent to nine Sheep, and one Cow to seven Sheep.

In Table XXVIII. Flock Expenditure has been analysed in further detail:—

TABLE XXVIII.—*Detailed Analysis of Mean Yearly Costs of Fat Lamb Flock (1922-30).*

Table XXIX. serves to show why the 1929-30 Season ended so disastrously for the Turretfield Flock. The value of the Wool per Ewe fell from a seven years' average of 15s. to 7s. 2d., representing a decline in values of £265 11s. for the whole Flock. Similarly, Inventory Debit differences, reflecting the general decline in Sheep values, rose from a seven years' average of 9s. 3d. to 20s. 6d. per Ewe, representing a decline in values for the whole Flock of £381 7s. 6d. In the aggregate, these declines in values represent a debit against the Flock of £646 18s. 6d., or 19s. 1d. per Ewe; on the other hand, the indifferent character of the season rendered necessary unusually heavy Hand Feeding, represented by a cost of 8s. 1d. per Ewe, as against a mean of 1s. 10d. for the preceding seven years. Relatively to preceding means, Hand Feeding would therefore have involved us in 1929-30 in additional expenditure of £211 17s. 6d.; the latter sum when added to the decline in Sheep and Wool values gives an unusual aggregate Debit of £858 16s. against 1929-30 Flock transactions. Had these three items been normal, the season would have closed on a Profit instead of a huge Debit Balance.

The unsatisfactory character of the 1929-30 season has had the effect of reducing preceding Revenue Means very considerably, namely, from 29s. 6d. per Ewe—the mean of the preceding seven years—to 27s. 3d.

## COST OF UPKEEP OF WORKING HORSES.

Apart from an occasional foal, Working Horses do not contribute anything directly to Farm Revenues, unless, indeed, circumstances compel the owner to take up contract work: Indirectly, however, through the power they supply, they must be looked upon as the mainspring behind farm production. Hence, an accurate determination of the

cost of this power is of paramount importance to all Farm Accounts; this determination, moreover, has acquired added interest in farm economics since the appearance of Tractors in our midst. I have summarised below in Table XXX. the cost of upkeep of Horses at Turretfield in 1929-30 in comparison with corresponding figures for 1922-29 and 1922-30 periods respectively.

TABLE XXX.—*Summarising Cost of Upkeep of Working Horses,*  
1929-30, 1922-29, and 1922-30.

|                                    | 1929-30.   |    |    | 1922-29.   |    |    | 1922-30.  |    |    |
|------------------------------------|------------|----|----|------------|----|----|-----------|----|----|

|                                    | 1,037 13 9 |    |    | 1,063 8 11 |    |    | 1,060 4 7 |    |    |
| Less Closing Valuation .....       | 358 0 0    |    |    | 433 6 0    |    |    | 423 17 10 |    |    |
| Net Cost of Upkeep ..              | 679 13 9   |    |    | 630 2 11   |    |    | 636 6 9   |    |    |
| Number of Horses ....              | 30         |    |    | 32.99      |    |    | 32.61     |    |    |
| Number of Horse-hours worked ..... | 30,918     |    |    | 30,402     |    |    | 30,466    |    |    |
| Cost of Horse-hour ....            | 5.28d.     |    |    | 4.97d.     |    |    | 5.01d.    |    |    |
| Cost of Horse eight-hour day ..... | 3s. 6.21d. |    |    | 3s. 3.8d.  |    |    | 3s. 4.1d. |    |    |

It will be observed that over a period of eight successive seasons the mean cost of upkeep of 32.61 Horses has been at the rate of 5.01d. per Horse-hour, or 3s. 4.1d. per eight-hour Horse day.

The relationship of the mean total cost of upkeep of 32.61 Working Horses at Turretfield—£636 6s. 9d.—to the mean area under crop, the mean area cultivated (crops plus bare fallow) and the total arable or farmed area is shown below:—

1. Mean inclusive cost of Upkeep of 32.61 Working Horses on 1,266 acres of arable land (38.82 acres per horse) . . . . . £636 6 9
2. Mean cost per acre of Upkeep of Horses in relation to mean area under crop (658 acres: 20.18 acres per horse) . . . . . 0 19 4
3. Mean cost per acre of Upkeep of Horses in relation to mean area cultivated (1,078 acres: 33.06 acres per horse) . . . . . 0 11 10
4. Mean cost per acre in relation to total arable area . . . . . 0 10 1

As a mean of 32.61 Horses have worked in the course of a year 30,466 hours, or 3,808½ eight-hour days, it follows that the mean effective work per Horse has been 117 days per annum.

The Mean Yearly Cost of Upkeep of Working Horses over eight consecutive seasons as set out in Table XXX. may be summarised as follows:—

|                           | Mean Cost of Upkeep of 32.61 Horses. |    |    | Mean Cost per Horse. |    |    | Percentage. |
|---------------------------|--------------------------------------|----|----|----------------------|----|----|-------------|
|                           | £                                    | s. | d. | £                    | s. | d. | %           |
| Wages .....               | 70                                   | 9  | 5  | 2                    | 3  | 2  | 11.1        |

| Grazing .....             | 54                                   | 1  | 4  | 1                    | 13 | 2  | 8.5         |
| Depreciation and Repairs  | 34                                   | 1  | 4  | 1                    | 0  | 11 | 5.3         |
| Sundries—                 |                                      |    |    |                      |    |    |             |
| Plus Inventory decreases, |                                      |    |    |                      |    |    |             |
| less Sales .....          | 38                                   | 4  | 0  | 1                    | 3  | 5  | 6.0         |
| Totals.....               | 636                                  | 6  | 9  | 19                   | 10 | 3  | 100.0       |

I have summarised in Table XXXI. Foodstuffs supplied and grazing areas made available to Working Horses in 1929-30 and in 1922-29 and 1922-30 periods respectively:—

TABLE XXXI.—*Summarising Foodstuffs supplied per Horse and Grazing made Available in 1929-30, 1922-29, and 1922-30.*

|                    | Units.     | 1929-30. | 1922-29. | Means.<br>1922-30. |
|--------------------|------------|----------|----------|--------------------|
| Cereal Hay Chaff.. | tons ....  | 3.47     | 3.48     | 3.48               |
| Long Cereal Hay .  | tons ....  | 0.57     | 0.29     | 0.32               |
| Oats .....         | bushels .. | —        | 5.53     | 4.89               |
| Barley .....       | bushels .. | —        | 2.54     | 2.25               |
| Grazing .....      | days.....  | 41       | 152      | 140                |
| Number of Horses.  | head ....  | 30       | 32.99    | 32.61              |

*Mean Foodstuffs per Horse per Day when not Grazing.*

|                    |           |       |       |       |
|--------------------|-----------|-------|-------|-------|
| Cereal Hay Chaff.. | lbs.....  | 23.99 | 36.60 | 34.65 |
| Long Cereal Hay .  | lbs.....  | 3.94  | 3.05  | 3.19  |
| Oats .....         | lbs.....  | —     | 1.04  | 0.87  |
| Barley .....       | lbs.....  | —     | 0.50  | 0.42  |
| Non-grazing days.. | days .... | 324   | 213   | 225   |

From the above it follows that when away from grazing areas Working Horses have been fed at Turretfield at the mean rate of 37.84lbs. of Cereal Hay Chaff and Long Hay, together with 1.29lbs. of Oats and Barley.

### THE COST OF PREPARATION OF FARM FALLOW.

As is generally the case in the settled areas of the State, Wheat crops in the Turretfield district, whether intended for grain or for hay, have usually been preceded by nine months or thereabout of well worked Bare Fallow. The costs involved by this practice vary considerably with the character of the soil, the depth of ploughing, the number of workings found necessary, and even with seasonal vagaries.

Turretfield costs in this direction have been shown below in Table XXXII. for 1929-30 Season in contrast with the Means of the 1922-29 and 1922-30 Periods respectively:—

TABLE XXXII.—*Summarising Expenditure incurred in Preparation of 1929-30 Bare Fallows in contrast with corresponding Means for 1922-29 and 1922-30.*

|                         | 1929-30.        |           |  | 1922-29.        |           |  | 1922-30.      |           |  | Percentage |
|-------------------------|-----------------|-----------|--|-----------------|-----------|--|---------------|-----------|--|------------|
|                         | Total.          | Per Acre. |  | Total.          | Per Acre. |  | Total.        | Per Acre. |  |            |
|                         | £ s. d.         | s. d.     |  | £ s. d.         | s. d.     |  | £ s. d.       | s. d.     |  | %          |
| Wages .....             | 109 9 10        | 4 7.8     |  | 90 18 9         | 4 4.0     |  | 93 5 2        | 4 5.3     |  | 16.0       |
| Use of Horses .....     | 320 13 4        | 13 7.5    |  | 253 13 7        | 12 3.6    |  | 262 1 0       | 12 5.7    |  | 44.9       |
| Use of Implements ..... | 58 18 10        | 2 6.0     |  | 47 5 9          | 2 3.5     |  | 48 14 11      | 2 3.9     |  | 8.4        |
| Rent (9 months) .....   | 184 11 4        | 7 10.1    |  | 163 12 2        | 7 11.2    |  | 166 4 6       | 7 11      |  | 23.5       |
| Rates and Taxes .....   | 16 9 7          | 0 8.4     |  | 12 6 1          | 0 7.1     |  | 12 16 6       | 0 7.3     |  | 2.2        |
| Inclusive Costs .....   | 690 2 11        | 29 3.8    |  | 567 10 4        | 27 6.3    |  | 583 2 1       | 27 9.2    |  | 100.0      |
| Areas Fallowed .....    | Acres.<br>470.9 |           |  | Acres.<br>412.6 |           |  | Acres.<br>423 |           |  |            |

It follows from the above that over eight consecutive seasons the inclusive costs of preparation of Fallows at Turretfield to March 31st of each year have been 27s. 9d. per acre, or 19s. 3d. exclusive of nine months' rent and proportionate Rates and Taxes.

### MEAN COSTS OF VARIOUS FARM OPERATIONS.

General Farming is an avocation involving numerous individual field operations, all of which contribute in varying degree to the financial success or failure of the season's work, and although in everyday practice actual costs of individual operations are rarely

taken into consideration, it is not without interest to place on record these costs, when accurate data are available for the purpose. The Turretfield Accounts have been kept in such a manner as to render possible the accurate determination of the costs of individual operations in any one season; and the means of these costs over a number of seasons may be taken to represent the position in Turretfield practice. I admit that Turretfield Means may not always agree with corresponding estimates that are sometimes given. In this connection I shall point out that with characteristic human optimism such estimates are usually based upon ideal conditions of work, that adequate allowance is rarely made for breakdowns, broken time, depreciation, &c., and that for the most part they do not correspond to every-day farm conditions. Data given below in Table XXXIII. are the means of costs incurred over large areas and continuous seasons, and for similar conditions can be accepted as reasonably accurate so long as they extend over three or more seasons:—

TABLE XXXIII.—*Summarising Costs of some individual Farm Operations at Turretfield.*

|                                             | Seasons. | Wages. |      | Horses. |      | Implements. |      | Sundries. |      | Total. |      |

## PART III.

## RECORD OF LIVE STOCK CARRIED ON AREAS AVAILABLE FOR GRAZING.

On any Farm upon which Live Stock is kept, available grazing areas admit of classification under the following headings:—

1. Permanent Pasture usually non-arable.
2. Arable land temporarily out of cultivation; this area may include both land left out of cultivation for the whole season and land which is being progressively fallowed on the close of Seeding Operations. For the latter case it has been assumed in these Reports that in any given year land which is being fallowed remains available for grazing for three months of the year.
3. Stubble land becomes available for grazing from the completion of Harvest Operations to the 31st of March; thereafter, unless broken up for cropping, it is classed in these Reports as arable land temporarily out of cultivation. Hence, it is assumed that the stubbles of Winter-sown crops are available for grazing for three months of the year.
4. Specially sown grazing crops; at Turretfield usually Oats.
5. Fallow grazing to maintain weeds in check, a practice which much to the detriment of perambulating Live Stock is frequently abused of.
6. Occasional feeding-off of over-rank crops liable to lodging or blighting off.

Data concerning the extent to which these various types of grazing have been utilised at Turretfield have been carefully recorded since 1924, and 1929-30 results have been contrasted in Table XXXIV., with corresponding figures for the 1924-29 and 1924-30 periods respectively. For the most part Sheep have been the main type of grazing Live Stock in use. To a limited extent, however, both Cattle and Horses have had access to the grazing areas, and in order to bring down the figures to a common grazing unit individual Horses have been assumed to be the grazing equivalent of nine Sheep and Cattle of Seven Sheep.

TABLE XXXIV.—*Summarising Data concerning Sheep-carrying Capacity of available Turretfield Areas.*

| Totals ....           | 806.62                                                | 796.76             | 798.39             | 0.99                                                   | 1.16              | 1.13              |

The foregoing statement shows that on a Farm of 1,533 acres in area, of which 1,266 acres are arable and 252 non-arable permanent pasture, an average of 1.13 Sheep per acre per annum has been successfully carried over six consecutive seasons on the area available for grazing—798 acres—or the aggregate equivalent of 902 Sheep per annum. Over the same period, on the other hand, the mean area under harvested crops has been 550 acres, and under Bare Fallow 409 acres.

In Table XXXV. expenditure incurred on behalf of the several grazing areas, inclusive of Rent, has been summarised for 1929-30 in contrast with corresponding figures for the 1924-29 and 1924-30 periods respectively.

TABLE XXXV.—*Summarising Expenditure incurred on Grazing Areas inclusive of Rent in 1929-30 and 1924-29 and 1924-30.*

| Pea Stubbles .....             | 2                      | 2·9  |    | 1        | 4·1  |    | 1        | 4·3  |    |
| Grazing Crops .....            | 21                     | 2·5  |    | 15       | 1·4  |    | 16       | 2·7  |    |
| Mean Expenditure per Sheep ... | 13                     | 2·7  |    | 9        | 5·8  |    | 10       | 0·4  |    |

Table XXXV. shows the mean value of grazing—1924-30—to have been equivalent to 10s. 0·4d. per Sheep grazed. Such a statement is, however, incomplete, since on any farm, particularly in early Winter, a certain amount of Hand Feeding must generally be resorted to; how heavy expenditure incurred in this direction was in 1929-30 has already been adverted to in another section of this Report. It is clear, therefore, that Hand Feeding costs should be added to normal expenditure incurred on the grazing areas. During the period under review—1924-30—inclusive costs of Hand Feeding have been as follows:—

*inclusive Costs of Hand Feeding, 1929-30, 1924-29, and 1924-30.*

|                 | 1929-30. |    |     | 1924-29. |    |     | 1924-30. |    |     |
|-----------------|----------|----|-----|----------|----|-----|----------|----|-----|
|                 | £        | s. | d.  | £        | s. | d.  | £        | s. | d.  |
| Per Flock ..... | 275      | 7  | 1   | 72       | 13 | 10  | 106      | 9  | 5   |
| Per Sheep ..... | 0        | 8  | 1·5 | 0        | 2  | 2·1 | 0        | 3  | 2·1 |

Hence, over six consecutive seasons Mean Feed Costs per Sheep have been represented on the one hand by 10s. 0·4d. for normal expenditure on grazing areas, and on the other by 3s. 2½d. for hand feeding costs, making an aggregate total of 13s. 2½d.

### GENERAL SUMMARY.

The salient features of this Report may be summarised as follows:—

#### PART I.: 1929-30 TRANSACTIONS.

1. The Turrethield Demonstration Farm has been run upon purely business lines since July, 1921.
2. The effective area of the Farm is 1,533 acres, of which 1,266 acres are arable, 252 acres milky pasture, and 15 acres occupied by buildings, yards, plantations, &c.
3. The main crop has been Wheat, immediately preceded by nine months of cultivated Bare Fallow, and followed, over a limited area, by Pease for grain and Oats for grazing purposes. The Pea stubbles have usually been sown to Wheat in the

succeeding season. Sheep have been the main type of revenue-earning Live Stock in use.

4. From the standpoint of both Crops and Pastures 1929-30 Seasonal conditions were even more unfavorable than in the immediately preceding season.

5. The mean Wheat yield was 16.69 Bushels per acre, as against 18.83 Bushels for the preceding eight seasons.

6. The inadequacy of the pastures led to handfeeding of Sheep at the rate of 8s. 1d. per Ewe, as against 1s. 10d. for preceding seven years; this has represented abnormal expenditure of £211 17s. 6d. against a Flock of 678 Ewes, or 6s. 3d. per Ewe.

7. For the second time in nine consecutive seasons the Balance Sheet closed on a Debit Balance, namely, £757 5s. Main contributing factors to the position were unfavorable character of the season, and fall in the prices of Wheat, Wool, and Sheep.

8. Accumulated Net Profits since 1921 aggregated on the 31st March, 1930, £1,461 1s., representing a Mean Annual Net Profit for nine consecutive years of £162 6s. 9d.

9. The original Capital value of Land, Improvements and Equipment was represented by £17,590 18s. 2d. This sum has been treated as a Loan, upon which interest has been paid yearly into the Treasury. This Loan has been reduced by £1,000 from Farm Earnings.

10. Net Farm Earnings, i.e., Revenue less Expenditure, but exclusive of Interest on Capital, totalled £8 13s. 7d. only in 1929-30, against Mean Earnings of £1,109 6s. 7d. for the preceding eight seasons. Similarly, in 1929-30 interest on Capital engaged was 0.05 per cent. only as against 6 per cent. for the preceding eight seasons.

11. Whilst the Turretfield Farm has cost the State nothing since 1921, it has, on the other hand, paid into the Treasury in the course of nine seasons the sum of £8,612 5s. 7d., representing interest on Loan and Overdraft and part repayment of Principal.

12. For the purpose of determining inclusive Farming Costs, Interest has been charged against the various accounts, not only on the original Farm Loan, but also on accumulated Net Profits, which have been treated as Turretfield Personal Capital. On March 31st, 1930, these combined interest dues aggregated £7,612 5s. 7d. and £721 3s. 8d. respectively.

13. Over nine seasons Capital items have been written down to the extent of £2,617 13s. 5d., or 39.1 per cent., of their original values.

14. Over eight successive seasons the mean cost of Board and Lodging for portion of the Staff has been at the rate of 22s. 4d. per week.

15. In 1929-30 Wages aggregated £1,141 18s. 10d., or 14s. 11d. per acre, as against £1,196 3s. 6d., or 15s. 7d. per acre for the preceding eight years.

#### PART II.: DETAILED ANALYSIS OF FARMING COSTS.

1. The mean (1921-29) Capital of the Farm has been represented by £18,637 19s. 10d., or £12 3s. 2d. per acre. In this total Land and Improvements stood for £9 4s. per acre, or 75.7 per cent. of the total; Tools and Plant for 15s. 9d., or 6.4 per cent.; Working Horses for 5s. 7d., or 2.3 per cent.; Revenue Earning Live Stock for 15s. 6d., or 6.4 per cent.; and Sundries for 22s. 4d., or 9.2 per cent.

2. Over eight consecutive seasons, inclusive farming costs at Turretfield have been at the mean rate of £4,261 17s. 4d. per annum, or £2 15s. 7d. per acre. Of this expenditure £3,208 0s. 2d., or £2 1s. 10d. per acre, has involved direct cash outgoings, whilst the balance—£1,053 17s. 2d., or 13s. 9d. per acre—has been absorbed by transfers, depreciation, and interest on Capital.

3. This Mean Expenditure has been met by a Mean Farm Output of £4,341 0s. 9d., or £2 16s. 8d. per acre, leaving a Mean Net Profit of £79 3s. 5d., or 1s. per acre. Towards this output Harvested Crops have contributed £2,679 12s. 9d., or 34s. 11d. per acre, and Live Stock £1,542 17s., or 20s. 2d. per acre. On the basis of areas actually occupied and used, Crops have contributed a mean of £3 13s. 3d. per acre and Live Stock £1 13s. 10d. per acre.

4. On the above data, it is calculated that in competent hands a personal Capital of £4,000 should suffice for the purchase, equipment, and working of a 1,000 acre Farm of the Turretfield type.

5. Over a period of eight successive seasons "General Expenses" that could not be debited against any particular account averaged £691 7s., or 9s. per acre, or again, 16.22 per cent. of Mean Inclusive Expenditure.

6. Over a period of eight successive seasons inclusive Costs of growing and harvesting a 19.46 Bushel Crop of Wheat sown on Bare Fallow have aggregated £4 14s. 8d. per acre, or 4s. 10d. per Bushel. In these costs actual field operations—fallowing, seeding, and harvesting—have absorbed £2 19s. 10d., or 3s. per Bushel, the balance meeting the claims of interest and incidental items.

7. In the Mean Costs of growing Wheat, Wages have been represented by 23s. 8d. per acre, or 1s. 3d. per Bushel; these costs would correspond to the Labor-Income of a farmer and family mainly responsible for manual operations, apart from any Net Profits that might accrue from the year's transactions.

8. In the mean costs of growing Wheat, Interest on Land and Improvements, Interest on Working Capital, and Depreciation on Improvements and Plant aggregate 1s. 8d. per Bushel. If to this sum we add Wages (exclusive of depreciation on living quarters), namely, 1s. 2d., we get a total of 2s. 10d. a Bushel, which when deducted from inclusive costs of 4s. 10d. leaves a balance of 2s. a Bushel. If, according to the views of some English Economists, the items enumerated, including 1s. 2d. for unpaid family labor, cannot legitimately be included in the costs of growing Wheat, then it would seem that even at 2s. a bushel the farmer and family exclusively responsible for manual operations could grow Wheat without personal loss. It is nevertheless difficult to understand how in the circumstances they would be in a position to feed and clothe themselves.

9. Over a period of eight years Mean Labor requirements of Wheat sown on Bare Fallow have been represented by  $17\frac{1}{2}$  hours per acre; or for a  $9\frac{1}{2}$  acre working day 1.84 days per acre; hence, under Turretfield conditions on the basis of 307 working days per annum one man could be responsible for 167 acres of Wheat.

10. The Mean costs of growing Wheat on Pea Stubbles have aggregated £3 7s. 7d., or 4s. 3d. a Bushel, for a 15.94 Bushel crop. Hence, under Turretfield conditions Wheat at 4s. 6d. a bushel would show a margin of profit if following Pease, but a loss if following Bare Fallow, notwithstanding heavier mean yields resulting from the latter practice.

11. Labor requirements of Wheat following Pease have been represented by 13 hours per acre; or 136 days for 100 acres of Wheat as against 184 days for Wheat sown on Bare Fallow.

12. Over eight consecutive seasons a  $1\frac{1}{2}$ -ton Crop of Cereal Hay sown on Bare Fallow has cost £5 6s. 5d. per acre, or 59s. 6d. per ton in the stack; these figures correspond to £4 10s. 4d. per acre, or 50s. 6d. per ton in the stook.

13. In a cost of 59s. 6d. for Hay in the Stack, Interest on Land and Improvements, Interest on Working Capital, and Depreciation on Improvements and Plant absorb 18s. 7d. per ton and Wages 18s. 10d.; the balance, 22s. 1d., covers all other expenditure.

14. The Labor requirements of a  $1\frac{1}{2}$ -ton Crop of Hay grown on Bare Fallow are represented by 26 hours per acre, or  $2\frac{1}{2}$  days, against 1.84 days for a corresponding Wheat Crop. The great bulk of the additional Labor is called for at Harvest time.

15. A  $1\frac{1}{2}$ -ton crop of Cereal Hay—usually Oats—sown on Cereal Stubbles has cost £3 17s. 10d. per acre and 59s. 6d. per ton in the stack, i.e., exactly the same price per ton as corresponding Hay grown on Bare Fallow. Labor requirements, on the other

hand, are represented by 2½ days per acre for Hay sown on Stubbles, as against 2½ days for Hay grown on Fallow.

16. A 21.22 Bushel crop of Oats sown on Cereal Stubbles has cost £2 15s. 4d. per acre, or 2s. 7d. per Bushel. Labor requirements have been 1.19 days per acre sown.

17. A 17.26 Bushel crop of Barley sown on Cereal Stubbles has cost £2 12s. 1d. per acre, or 3s. per Bushel. Labor requirements have been 1.16 days per acre sown.

18. A 13.23 bushel Crop of Field Pease sown on Cereal Stubbles has cost £4 per acre, or 6s. 1d. per Bushel.

19. Labor requirements of the Field Pease crop have been represented by 15.53 Hours per acre, or 163 days for 100 acres. If we add these days to the 136 days required by the succeeding Wheat Crop, we get Labor requirements of 299 days for 100 acres of the Pease-Wheat Rotation as against 184 days only for corresponding area of normal Bare Fallow-Wheat Rotation. It follows that the Pease-Wheat Rotation offers greater advantages from the viewpoint of the employment of family Labor.

20. Over a period of eight successive years Mean Expenditure incurred for a Fat Lamb Flock averaging 614 Ewes has aggregated £791 4s. 9d. exclusive of Flock Depreciation, or 25s. 10d. per Ewe. In this total Wages have been responsible for 4s. 8d. per Ewe, or 18.1 per cent.; Feed, 14s. 2d., or 54.8 per cent.; and Incidentals, 7s., or 27.1 per cent.

21. Mean Gross Revenue has been at the rate of 38s. per Ewe, which after deduction of Mean Inventory differences leaves a Net Revenue of 27s. 3d., and a Net Profit of 1s. 5d. per Ewe only.

22. The 1929-30 Flock Debit Balance is shown to be attributable to the following items:—Decline in Wool values, £265 11s.; Decline in Sheep values, £381 7s. 6d.; abnormal Hand Feeding owing to unfavorable season, £211 17s. 6d.; representing in the aggregate abnormal expenditure of £858 16s., or 25s. 4d. per Ewe.

23. Over the eight seasons Mean Mortality of the Flock has been at the rate of 5.3 per cent. per annum.

24. Mean cost of Upkeep of Working Horses at Turretfield has aggregated 3s. 4d. per eight-hour day worked, or £19 10s. 3d. per annum. This figure corresponds to 19s. 4d. per acre on the mean area under crop, or 11s. 10d. on the mean area cultivated (crops plus Bare Fallow).

25. Over eight consecutive seasons the mean number of eight-hour days worked has been 117 per Horse.

26. The Mean Inclusive Cost of Farm Fallows to March 31st of each year has been 27s. 9d. per acre, or 19s. 3d. per acre, exclusive of nine months' rent and proportionate rates and taxes.

27. A Table has been prepared setting out mean costs of various individual farm operations in which Turretfield has been concerned.

### PART III.: RECORD OF LIVE STOCK CARRIED ON AREAS AVAILABLE FOR GRAZING.

1. Over six consecutive years the mean area available for grazing at Turretfield has been equivalent to 798 acres, or 52.1 per cent. of the total area of the farm; and over this period this grazing area has carried the equivalent of 1.13 Sheep per acre per annum.

2. Similarly, over the same period expenditure incurred upon the available grazing area, inclusive of Rent and Proportionate Rates and Taxes, has been at the mean rate of 10s. per Sheep. To this figure should be added mean Hand Feeding costs, namely, 3s. 2d. per Sheep, representing an aggregate cost, therefore, of 13s. 2d. per Sheep.

It remains for me to express appreciation of the efficient manner in which the Manager (Mr. F. E. Waddy) has attended to his duties and for the thoroughness with which the Accountant and Staff have prepared the material upon which this Report has been based.

## THE CHAMPIONSHIP WHEAT CROP COMPETITION.

[Won by Mr. H. C. M. PILGRIM, Wolseley.]

In his report on the Championship Wheat Crop Competition for the season 1930-31, Mr. W. J. Spafford (Deputy Director of Agriculture), who judged the entries, stated that for the past seven years Wheat Crop Competitions, supervised by the Department

of Agriculture, have been conducted in South Australia. For the first six seasons the Government subsidised these competitions, but unfortunately found it necessary to discontinue the subsidy for the past season, with the inevitable result that the number

of entries received showed a decrease on previous years. The Department of Agriculture supplies the judges to inspect the crops and make the awards and to prepare reports on all entries in the competitions.

Although the drought being experienced in the State continued unabated during the season 1930-31, and despite the fact that no subsidy was available, the interest in these competitions was maintained to a remarkable extent, and 19 of the 24 Crop Competition Districts conducted competitions, and 473 crop entries were submitted to the judges.

*Table Showing Progress of Wheat Crop Competitions.*

| Year.          | Districts Conducting Competitions. | Number of Crops Exhibited. |
|----------------|------------------------------------|----------------------------|
| 1924 . . . . . | 12                                 | 290                        |
| 1925 . . . . . | 13                                 | 248                        |
| 1926 . . . . . | 17                                 | 444                        |
| 1927 . . . . . | 19                                 | 525                        |
| 1928 . . . . . | 22                                 | 634                        |
| 1929 . . . . . | 21                                 | 520                        |
| 1930 . . . . . | 19                                 | 473                        |

In 1927 the Royal Agricultural and Horticultural Society offered as a prize in connection with Wheat Crop Competitions, conducted under the auspices of the Department of Agriculture, a silver challenge shield of the value of 50 guineas, and annually a small replica of the shield valued at five guineas. The Royal Society had in view the offer of special assistance in the encouragement of Wheat Crop Competitions, and in accepting the generous offer, the Government agreed to conditions laid down by the society, which were as follows:—

1. The prizes to go to the person exhibiting the best crop in the competitions supervised by the Department of Agriculture—the silver challenge shield for a period of 12 months immediately succeeding the award and the silver replica to become the absolute property of the winner.

2. The challenge shield, with the name of each year's winner engraved thereon, to be exhibited in the Town Hall or Institute nearest the farm on which the winning crop was grown.

3. The crop awarded first prize in each supervised district competition to be taken as an entry for the Championship Competition, except in any case in which it is thought by the judge of the district competition that the winning crop is not of sufficient merit to warrant inspection for the championship trophy.

4. All entries for the championship to be inspected by one judge. Such inspection to be undertaken in each district soon after the district judge has made his awards, but not before the crop has ripened.

5. Each competitor for the championship to be required to stage one bag of grain and one sheaf (about 1ft. in diameter) of grain in the straw at the Royal Spring Show following the competition.

#### THE ENTRIES.

In such a bad season and when no monetary assistance was forthcoming to help the competition committees, it was anticipated that there would be a considerably reduced number of competitors likely to have a crop in the Championship of the State Competition, but this did not prove to be so, and eventually 13 crops were judged for this valuable trophy, most of them being very high-class wheat crops.

#### *Previous Winners of the Championship Wheat Crop.*

1927—F. V. Trenorden, Bordertown (Federation wheat).

1928—F. Coleman, Saddleworth (Leak's Rustproof and Fondling wheats).

1929—F. V. Trenorden, Bordertown (Bena wheat).

## THE AWARDS.

In reporting on the entries, it has been decided to follow the practice of other years of indicating the crops which would have been placed second and third to the winner of the championship trophy had this been an ordinary competition, but the other crops are not shown in order of merit, and where any remarks are made on their crops the exhibitors' names are placed in alphabetical order and not according to points awarded. The awards and a brief description of the crops submitted in the competition are set out below:—

## THE CHAMPIONSHIP WHEAT CROP.

*H. C. M. Pilgrim, Wolseley.*

The winner of the championship wheat crop was Mr. H. C. M. Pilgrim, whose crop of Free Gallipoli wheat was placed first in the Tatiara Crop Competition, and his success means that on three of the four years since the championship was inaugurated the coveted trophy has been secured by a crop grown in the Tatiara district. The block of wheat was a really wonderful competition crop, showing every evidence that the very best farming methods are practised by the grower. It was a very clean crop, only containing a few patches where wild oats were rather heavy and a few isolated plants of King Island melilot and sheep weed. Some red rust was visible on the plants, but the attack was so light that the grain was unaffected and was of good quality. The outstanding features of the crop were the heavy yield of grain, the absence of strangers, and its wonderful evenness. The crop was remarkably true to type, and great difficulty was experienced in finding any other variety in the whole block. Other than a small portion in the north-east corner having lodged a little, it was a beautifully even and regular crop, standing up well to the large, well-filled heads.

The block of land which carried the crop grew oats in 1925, was in pasture in 1926, fallowed in 1927, was under wheat in 1928, and was bare fallowed in 1929, and received very thorough working throughout the fallowing period. The land was ploughed about 3½ in. in depth during April, was harrowed in about a month's time, cultivated and harrowed at the end of June, again had the double working at end of August, and end of October, was harrowed in early December and again at the end of that month, and was cultivated and harrowed at the end of February. In due season it was prepared for seeding, which was carried out at about June 1st, when 60 lbs. seed, which had been pickled with copper carbonate, was drilled in to the acre with 92 lbs. superphosphate (45 per cent.). For a "dry" season the amount of soil working carried out proved highly advantageous, and it must have had a lot to do with the very satisfactory manner in which this crop matured, for there were no evidences of "take-all" or "blighting" through the plants having ripened too rapidly, as was to be seen in many parts of the State this season.

## THE OTHER PLACED CROPS.

*R. J. Cliff, Anama.*—This heavy-yielding crop of Nabawa wheat, which won the Midlands Crop Competition for Mr. R. J. Cliff, was an attractive and in most ways an excellent competition crop. It was very free from weeds, except for a sprinkling of barley throughout the crop and small patches of a variety of weeds in a few crab-holes where the crop had been drowned out. Red rust was plentiful in the plants, but the grain was not injuriously affected, except in the small, second-growth heads. There was a sprinkling of a dark-headed wheat throughout the crop, but on the whole it was nice and true to type. There was some noticeable variation in the regularity of the crop, due to changes of soil type, and some of the heavier portions had lodged, but it was fairly even, nevertheless.

In 1928 the land on which the crop was grown was still unbroken pasture land carrying black-grass tussocks, and this was fallowed during 1929. The block was ploughed about 4 in. in depth in July, harrowed down in August, cultivated twice in

September and twice in October, and cultivated and harrowed in April. In the third week in May 75lbs. of seed was drilled in to the acre with 70lbs. superphosphate (45 per cent.).

The fact that the land had been grazed by sheep for many years and was carrying its first cultivated crop must have played some part towards the production of such a good block of wheat, but the cultivation, leading as it did to the reconsolidation of the land, was a very important factor, and Mr. Cliff is to be congratulated on this highly creditable exhibit.

*T. W. Roenfeldt, Greenock.*—It was a block of crop composed in part of Late Gluyas and the remainder of Ford with which Mr. Roenfeldt secured first prize in the Central District Crop Competition. Both varieties were nice and free from weeds, except that there was a sprinkling of oats in the Late Gluyas, quite a lot in the Ford, and a little barley was found in each. The Late Gluyas carried a fair amount of red rust, still the grain was really good, while the Ford appeared to be disease free. The two kinds were nice and true to type, containing only a light sprinkling of strangers. At the time of judging both varieties were shedding some grain and patches of the Ford had lodged rather badly. Just as they ripened they must have been lovely crops, but the shedding and lodging had rather tended to spoil them.

The land carrying the competition crops had been worked on the bare fallow-wheat rotation for a number of years. In 1929 it was ploughed with a mouldboard plough in June-July, harrowed down in August, cultivated in September, cross-cultivated in October, harrowed in December, cultivated in January, and harrowed in April. It was then prepared for seeding, and in mid-June 90lbs. of seed were drilled in to the acre with superphosphate, one portion receiving 2cwt. of 48 per cent. and the remainder 100lbs. of 100 per cent. per acre.

#### OTHER ENTRIES (in Alphabetical Order).

*H. E. Aldenhoven, Arthurton (Sepoy).*—At one time this crop of Sepoy, which won the Northern Yorke Peninsula Crop Competition, promised to yield over 45bush. per acre, but although it was not seriously diseased, it matured with unnatural rapidity, and the grain was so badly pinched as a consequence that the returns were appreciably reduced. It was a fairly clean crop, still, wild oats were heavy in patches and there were just a few weeds of other kinds. A little red rust was noticeable, but not sufficient to lead to the "closing up" of the crop. The crop had a fairly heavy infestation of strangers. Although a little lighter on the limestone outcrop, this was a very even and regular crop. The original stirring and practically all the workings of the fallow were given with a spring-time cultivator. The seeding was carried out during the first week in July, when 70lbs. of seed were drilled in to the acre with 1cwt. superphosphate (45 per cent.).

*E. J. Beinke, Kimba (Gluyas).*—This was a very clean crop of Gluyas which won the Buxton Crop Competition, as it only contained a few scattered plants of mustard, and only a single plant of barley was seen. Quite a lot of flag smut was found as well as a good deal of red rust, still the grain was not shrivelled in the least. There was too much admixture of other varieties and, except for that, it was a nice, fairly even crop, but rather on the light side. The land on which the crop was grown was fallowed in July after having carried an oat crop the previous season and was sown in May with 60lbs. seed and 90lbs. superphosphate (48 per cent.) per acre.

*Eagle Bros., Wandearah (Gluyas).*—The Western Crop Competition was won by this crop of Gluyas, which was nice and clean except for the presence of a lot of barley and just a little of a few other weeds. There was a fair sprinkling of flag smut, but worse still was the presence of so much red rust, particularly on the late patches, that the grain was on the thin side. The crop was far from being true to type, and it was only fairly even, some patches being really heavy and had lodged, whilst some small

patches were rather light. The land, which for some years has been worked on the bare fallow-wheat system, was disc ploughed in August, cultivated in October, and harrowed on several occasions. The seeding was done in June with 60lbs. seed and 60lbs. superphosphate per acre.

*Mrs. F. Hartmann, Monarto South (Currawa).*—Mrs. Hartmann won the Southern Crop Competition with a crop of Currawa which was fairly clean, but the wild oats were heavy in places. There was a sprinkling of barley throughout the crop and a few other weeds. Quite a fair amount of red rust was present, but without pinching the grain. There was a little flag smut, and odd plants were affected with loose smut. There was a light sprinkling of strangers in the crop and the northern headland was not cut right out, and so there was a heavy sprinkling of a brown-chaffed wheat along this edge of the crop. Although there were some variations due to different soil types, this was a fairly even crop. The field has been worked on the three-course system of pasture-fallow-wheat for some time. The fallowing was done with a mould-board plough in June, harrowed in August, and then kept cultivated throughout the season with a spring-tine cultivator. The seeding was done at the end of June with 65lbs. seed and 120lbs. superphosphate (45 per cent.) per acre.

*Henderson Bros., Maitland (Ford).*—This is the second year in succession that Messrs. Henderson Bros. have won the Mid-Yorke Peninsula Crop Competition, and on both occasions it was with a crop of Ford wheat. This year they exhibited a heavy-yielding crop which was really clean, containing only a few plants of several different weeds, the only bad one of which was drake. The whole crop was practically free from disease, there being only a few spots of red rust visible. There were too many strangers present to class the crop as being above fairly true to type. It was a fairly regular crop, producing good grain and in every way, except trueness to type, was a good competition crop. The field in which the crop was grown has been worked on the system of fallow-wheat-second cereal for several years, and after being ploughed the fallow was broken down with a cultivator, and was worked several times during the season with spring-tine cultivator and harrows, but particularly with the latter. Ninety pounds of seed were drilled in to the acre in early July with 120lbs. superphosphate.

*J. J. Honner, Sen., Brentwood (Currawa).*—This crop of Currawa which was grown at Warooka, gained first place in the Southern Yorke Peninsula Crop Competition, and was a fairly grainy crop, but contained a lot of weeds, including a fair sprinkling of barley, and was also affected with bunt and a little red rust. There was a little admixture of other varieties, but the crop was fairly true to type. It was a fairly even crop and had developed really good grain. The three-course system of fallow-wheat-barley had been practised for some years, and in 1929 the fallowing was done in July with a cultivator; it was double-harrowed in both July and August, was cultivated in October and March. Seeding was done about June 20th, when 90lbs. seed and 1cwt. superphosphate were drilled in to the acre.

*A. J. A. Koch, Lameroo (Sultan and Gluyas).*—The Chandos Crop Competition was won by this crop of Sultan and Gluyas. The Sultan was a very clean crop with just a few isolated weeds, as was the Gluyas also, except that there was a sprinkling of barley right through it. A lot of red rust was on the Sultan, whilst the Gluyas had only a few spots visible, but both kinds ripened too rapidly, and as a consequence the grain was really poor. The Sultan was nice and true to type and the Gluyas was very fair. The Sultan was the more even of the two, because the Gluyas contained some heavy, tangled patches. The land had been farmed on the fallow-wheat-oats system for some time. The seeding was carried out during the first week in July, when 60lbs. to 75lbs. of seed were drilled in with from 89lbs. to 100lbs. superphosphate (45 per cent.) per acre.

*G. W. Proctor, Yeelanna (Ford).*—A nice block of Ford won the Flinders Crop Competition for Mr. Proctor, it being a clean crop except for hop clover, and spear-

thistle, and small numbers of a few other weeds. There were a few patches of "take-all" and a little red rust, but the sample was good. It was fairly true to type, although a little brown-chaffed wheat was scattered throughout the crop. Despite the "take-all" patches, it was fairly even and regular. The system of farming practised for some years on this block of land has been that of fallow-wheat-pasture. The seeding was done at the end of May with 60lbs. seed being drilled in to the acre with 120lbs. superphosphate (48 per cent.).

*Sanders Bros., Yurgo* (Caliph).—This exceptionally clean crop of Caliph wheat, which won the Russell and Buccleuch Crop Competition, had hardly a single weed in it. Red rust developed so rapidly in the crop as it approached maturity that the grain was very much shrivelled. There was a light sprinkling of other kinds, still, it was very fair as regards trueness to type, and it was fairly even and regular. The block of land which carried the crop was still under mallee scrub in 1926, carried wheat in 1927 and 1928, and was fallowed in 1929. The block was fallowed in July, and between that time and seeding was cultivated five times and harrowed once. During the first week in June 45lbs. seed and 130lbs. superphosphate were drilled in to the acre.

*E. Smart, Gulgare* (Ford).—For the third time in the past four years a crop of wheat grown on this farm has won the Mid-North Crop Competition, and this year's crop of Ford again showed every indication of good farming methods. The crop was almost weed free, containing only a few very small patches of wild oats. There were a few spots of red rust, otherwise it was disease free. It was fairly true to type and was nice and even. Unfortunately, this otherwise well-grown and very attractive competition crop produced poor quality grain, because it matured so rapidly that it changed directly from the green stage to ripeness without developing that rich golden color which is characteristic of normal maturing. The land has been worked for some years on the simple system of fallow-wheat, and in 1929 the ploughing was done in the last week in June; it was cultivated in July, harrowed, cultivated, and harrowed in August, cultivated and harrowed at the end of September, bar-scraped at the end of January, cultivated in March and again in June. On about July 8th 85lbs. of seed and 87lbs. of superphosphate (48 per cent.) were drilled in to the acre.

Only one other wheatgrower in the State (Mr. F. Coleman, of Saddleworth) has put up the wonderful performance of having had three crops in the Championship Wheat Crop Competition, which has only been conducted for the past four years. Such an achievement is a very clear indication that the farmers are outstandingly skilful as wheatgrowers, and their methods could with advantage be followed by others similarly situated.

## NATURAL AND FEDERAL DISABILITIES OF SOUTH AUSTRALIA, VIEWED AS AN ESSENTIALLY AGRARIAN STATE.

[By ARTHUR J. PERKINS, Director of Agriculture.]

*(Evidence given at Adelaide before the Commonwealth Joint Committee on Public Accounts, January, 1931).*

South Australia is without exploitable Coal deposits, and it follows that industries, social services involving the use of Power, Rail transport, and incidentally costs of rural production, are in some degree controlled by those from whom Coal is procured; nor has it permanent running waters from which Power might be economically derived. Again, apart from Copper deposits which at present are lying dormant, Gypsum, Salt, and limited Iron Ore deposits, it lacks mineral resources of any great importance. South Australia has no natural forests of appreciable commercial value, and its only permanent watercourse is the lower reaches of the River Murray. The logical corollary to these natural disabilities is a present-day lack of population in proportion to territory effectively occupied, and it must be admitted that natural conditions, quite as much as the Federal tie, have compelled South Australia to develop, in the main, along agricultural and pastoral lines. But apart from these natural disadvantages, the cumulative pressure of 30 years' Federal fiscal policy upon rural production in South Australia has been very severe. The avowed aim of this policy has been industrial self-sufficiency of a handful of people, and it has operated very much to the disadvantage of South Australia, the solvency of which as a State is ultimately dependent upon its ability to export rural produce at a profit. I shall support this statement by the following considerations:—

In the first place, it must be fairly obvious that a community depending so largely upon rural output for home expenditure and commitments abroad must be economically able to face World competition and to accept World prices, coupled with corresponding parity for home consumption. In other words, without loss to itself it must be able to sell in the cheapest markets. In such circumstances, its solvency would appear to rest upon corresponding ability of its primary producers to buy in the cheapest markets; nor is this possible except under the incidence of a revenue or low tariff policy. Unfortunately, from the standpoint of South Australia, and that of other rural States, Federal Fiscal policy has, from its inception, been one of High Tariffs, the height of which has progressively risen from period to period, culminating in the all but prohibitive rates of 1930.

What have been the outstanding effects of this policy? It has assisted to build up two huge cities—Sydney and Melbourne—and in the process it has forced up costs of rural production to such an extent that it is becoming increasingly difficult to dispose of Australian rural produce at a profit to producers on the markets of the World.

Between 1901 and 1929 the population of Sydney rose from 487,900 to 1,238,660, and that of Melbourne from 494,129 to 1,018,200, that is to say, increases of 154 per cent. and 106 per cent. respectively over a period of 28 years.

Again, the value of the yearly output of the factories of New South Wales and Victoria rose between 1907 and 1928—a period of 21 years—from £66,924,646 to £309,868,401, representing an aggregate increase in value of £242,943,755, or 363 per cent. above 1907 values.

It would appear, therefore, that the factories of our two large cities have flourished exceedingly behind the High Tariff Wall of Federal Policy, but unfortunately, apart from articles of Primary Production, such as Butter, Cheese, Flour, &c., their enormous and costly output has not proved exportable, and has in the main been reserved for Australian Home consumption. And however much their own private interests may have been injured thereby, Australian consumers and users have been compelled to purchase these locally manufactured articles at prices considerably in excess of World parity, with crippling results upon general Costs of Production. In this connection the following figures from the Commonwealth Year Book are illuminating. The total value of Commonwealth Exports for 1927-28 is given as £138,947,447, of which £134,158,348 represented Primary Produce and £4,789,099 manufactured articles other than primary products, or 3.4 per cent. of the total only. Hence, the infinitesimal value of locally manufactured articles, other than primary produce, from the standpoint of our commitments abroad should be fairly obvious.

The immediate effects of high tariffs would seem, therefore, to be that those on the wrong side of the Tariff Wall are forced to pay considerably more than World parity for articles manufactured in their midst, and under a drag-net Tariff of the type we have recently experienced the cumulative result is an inevitable all round increase in the cost of living, which in its turn leads sympathetically to progressive increases in the cost of Wages. The latter then become responsible for further increases in the necessities of life and industry generally, and are ultimately reflected in progressively increasing costs of Rural Production, upon which rests precariously at the present time the whole superstructure of the State.

In the years that immediately succeeded the War, the insidious rise in costs of rural production was to some extent masked by a brief period of unusually high prices for rural produce. This period has now come to an abrupt end, and I hold firmly to the belief that an important, if not the main factor behind the crisis through which South Australia is passing, and indeed, to a less degree, the Commonwealth as a whole, is the fact that World prices for primary products no longer balance our artificially swollen costs of production. This unfortunate position is attributable both directly and indirectly to a relentless policy of prohibitive tariffs; and since as a State we have not the advantages of the accumulated wealth of locally protected manufactures, and have to pay toll to the industrialised States for the necessities of life and industry, the Federal Government cannot, in my opinion, escape the responsibility for a position very largely of its own creation.

The time at my disposal does not permit of a detailed examination into Costs of Production of the various phases of rural activity, and I shall have to content myself with a few typical examples with which I am familiar.

Wheat, because of its ready adaptability to our conditions of climate and soil—and, prior to Federation, it could have been added to our economic conditions as well—Wheat looms very large in the history of the State. Indeed, together with Wool, we may be said to owe to it whatever development we have hitherto attained to. It follows, therefore, that anything relating to its Costs of Production is of paramount importance to the State, and indeed to a less degree to the Commonwealth as a whole. Unfortunately, the determination of a mean figure applicable to the State as a whole is an exceedingly difficult, if not impossible, proposition; these costs must necessarily vary from district to district, from farm to farm, and even from season to season on one and the same farm. Nevertheless, in existing circumstances, I do not believe that anyone could be found with any real knowledge of the question who would maintain that 2s. per bushel and less on the farm could possibly meet current costs of production. I have been responsible for a Government Farm (Turretfield) which for nine successive years has been run from its own revenues without the assistance of a Government grant, and during the course of which all expenditure has been submitted to

detailed analysis. I append, as a contribution to the subject, itemised statements of actual Costs of Production of Wheat over eight successive seasons, during the course of which the mean yield per acre was 19.64bush.

| All other costs .....                                         | 1 7 6  | 1 4  | 29.1  |
| Inclusive Costs .....                                         | 4 14 8 | 4 10 | 100.0 |

I lay no claim for these costs that they are necessarily representative of South Australian mean conditions. They are, however, the only authentic ones at present available, and I do claim that for a mean average yield of 19½bush., and on a farm on which the land is heavy to till and management and labor are paid for in Cash, Costs both per acre and per bushel are reasonably accurate. These costs imply that on a farm wholly worked by the owner and his family, Wheat at 4s. 10d. per Bushel, besides yielding reasonable interest on Capital invested and providing for depreciation, leaves to the farmer and family a Labor Income at the rate of £1 3s. 8d. per acre under Wheat, or of 1s. 3d. per Bushel reaped. Two shillings a bushel, on the other hand, would pay neither interest, depreciation, nor wages, but on a 19½bush. harvest would suffice to meet all other costs.

It is true that in many parts of the State the rental value of the land is less than at Turretfield and tillage operations less costly, but, on the other hand, mean yields per acre are also correspondingly lower. Hence, whilst mean costs per acre would certainly be lower—possibly as low as £3—there would be little or no difference in mean costs per bushel; a 12bush. crop costing £3 per acre would represent a corresponding cost of 5s. per Bushel.

Finally, I shall add that most of the items included in the Costs of Production of Wheat admit of appreciable reductions under a policy of Low Tariffs. Indeed, I am prepared to go as far as to say that if Port Adelaide were a free port, even Wheat at 2s. a Bushel would not necessarily prove a losing proposition.

In 1913 I had occasion to put on record current values for farm machinery, essential material, tools, &c. These values are shown below in contrast with corresponding 1930 figures:

|                                                    | 1913. |    |    | 1930. |    |    | Percentage |
|----------------------------------------------------|-------|----|----|-------|----|----|------------|
|                                                    | £     | s. | d. | £     | s. | d. | Increases. |
| Essential Farm Machinery ...                       | 518   | 17 | 0  | 826   | 19 | 4  | 59.4       |
| Farm Harness .....                                 | 21    | 16 | 9  | 31    | 1  | 8  | 42.3       |
| Miscellaneous Tools .....                          | 3     | 9  | 3  | 6     | 3  | 1  | 77.7       |
| Other material essential to<br>Wheat growing ..... | 91    | 13 | 0  | 113   | 7  | 11 | 23.7       |
| Totals .....                                       | 635   | 16 | 0  | 977   | 12 | 0  | 53.6       |

Hence, on the items indicated above alone, purchase costs since 1913 have increased by 53.6 per cent., and allowing 16 per cent. for Interest and Depreciation these increases would represent on an average farm an additional yearly charge of £54 13s. 9d., or an additional cost of 4d. to 5d. per Bushel on a 3,000bush. Harvest.

How heavily interest and depreciation charges weigh upon the farmer, and more particularly upon the farmer handling relatively small areas, was made clear in a recent inquiry which I made into Capital invested in South Australian Wheat Farming. Figures given below summarise the position, apart from interest on land or rent.

*Estimated Mean Interest and Depreciation on Improvements and Working Plant on Farms of Varying Dimensions.*

|                        | Mean Areas. | Assumed<br>Mean Yield<br>per Acre. | Mean<br>Interest<br>and<br>Depreciation |
|------------------------|-------------|------------------------------------|-----------------------------------------|
|                        |             |                                    | per Bushel.                             |
|                        | Acres.      | Bush.                              | s. d.                                   |
| Very Small Farms.....  | 287         | 18.87                              | 2 2                                     |
| Small Farms .....      | 633         | 17.78                              | 2 0                                     |
| Average Farms .....    | 988         | 14.05                              | 1 11                                    |
| Large Farms .....      | 1,651       | 11.86                              | 1 10                                    |
| Very Large Farms ..... | 3,077       | 10.00                              | 1 9                                     |

The above figures are based upon an inquiry into the position of 129 South Australian Wheat Farms. It will be observed that interest and depreciation charges on improvements and working plant are practically equivalent to current prices for Wheat. The uneconomic height to which these charges have attained is one of the consequences of a high tariff policy.

In 1927 I had occasion to keep the accounts of a prominent Dairyman situated on the River Murray Reclaimed Swamp Lands, and notwithstanding the fact that for the year his Herd averaged more than 1,000galls. of Milk for every Cow in the herd, the inclusive Costs of the Milk produced were a shade under 9d. per gallon.

I recognise freely that South Australia is not the only State dependent upon rural output for continued prosperity; and although this dependence may not be quite as great as our own, the Commonwealth might perhaps justly be described as a federation of rural States with two highly industrialised Cities. And the recent appeal of the Prime Minister for maximum Wheat Production throughout the Commonwealth may be accepted as a welcome federal awakening to the major importance of rural production in our Common Economic life. But unfortunately even in this matter of rural production we have special difficulties of our own which tend to place South Australia at a disadvantage relatively to the better endowed Sister States, and to these difficulties I propose now drawing attention.

It is a well recognised fact that over the bulk of Australia Rainfall and its seasonal distribution dominate Crop Production and the relative abundance of grass or Livestock carrying capacity of the land. In this connection, out of territory 380,070 square miles in area, 310,660 square miles or 81.7 per cent. of South Australia receive less than 10in. of yearly Rainfall and lie therefore outside normal cropping areas. Corresponding percentages for land outside the 10in. rainfall line for Sister States are as follows:—Western Australia, 49.9 per cent.; New South Wales, 15.7 per cent.; Queensland, 12 per cent.; whilst in Victoria and Tasmania a rainfall in excess of 10in. is received by each State throughout their respective territories. It must be clear, therefore, that in South Australia the available cropping area is very much restricted by unfavorable rainfall conditions.

Again, of the country receiving in South Australia 10in. and more of rain, a limited proportion only is suitable for agricultural operations. In this connection it is estimated that not more than 15,000,000 acres can be described as arable land, that is to say, 33.8 per cent. only of the land receiving 10in. and more of rain and 6.4 per cent. only of South Australia's total territory.

Moreover, of our arable area in the neighborhood of 10,000,000 acres, or two-thirds of the total is "Mallee Land," and as such of relatively low natural fertility. It is this fact that tends to keep our mean Crop yields at a relatively low level and to make it extremely difficult for at least 50 per cent. of our farmers to face artificially raised costs of production, and their personal straits are reflected in the financial difficulties of the State.

Another serious difficulty is the absence of good underground water supplies for Livestock and other purposes over the greater part of South Australia. This has rendered necessary the building up of costly reservoirs with attendant reticulation systems to meet the needs of an extremely scattered population, and the building and upkeep of these national works has been a heavy burden on State finances.

Our pastures generally and our hot, dry summers do not lend themselves generally to Dairying, except with the costly assistance of hand-feeding over six months of the year, and we have usually found ourselves compelled to import butter for home consumption over portion of the year. This disability has hitherto hampered our attempts at closer settlement. Apart from the very limited areas of Reclaimed Murray Swamps and portions of our Hills Districts, the only important tract of country likely to prove suitable for Dairying is situated in the South-Eastern Statistical Division of the State. Unfortunately much of the latter country is usually under water in Winter and has already involved the State in heavy expenditure for drainage, and is likely to cost a good deal more before the work can be completed.

It is true that we possess important tracts of country admirably adapted to fruit and vine-growing, whether under irrigation or conditions of natural rainfall. Unfortunately, the federal high tariff policy has forced up Costs of Production to such an extent that to-day it is no longer possible to market fruit and fruit products overseas to any great advantage. The unenviable position of the canned and dried fruit industries is a case in point. To these might be added the stagnation of the Olive Oil industry, which is barely able to face foreign competition on the home market, although admirably adapted to local conditions of climate and soil, and which prior to federation appeared to be full of promise for the State. But with the cost of mere picking in the neighborhood of £5 a ton, it is little wonder that Olive growing is looked at askance by would-be growers. And it is analogous reasons that prevent us from developing a profitable overseas trade in Pig Products.

Finally, our high Railway rates which are partly one of the consequences of the scattered nature of our land settlement and partly one of the consequences of a high

tariff policy, are very burdensome upon local rural production. These rates are relatively heavier than in neighboring States as the following examples will show:—

|                         | Wheat.                        |                                | Superphosphate.              |                               |
|-------------------------|-------------------------------|--------------------------------|------------------------------|-------------------------------|
|                         | 1st 50<br>Miles.<br>Per Bush. | 1st 100<br>Miles.<br>Per Bush. | 1st 50<br>Miles.<br>Per Ton. | 1st 100<br>Miles.<br>Per Ton. |
|                         | d.                            | d.                             | s. d.                        | s. d.                         |
| South Australia .....   | 2-97                          | 4-43                           | 5 5                          | 9 8                           |
| New South Wales .....   | 2-53                          | 3-89                           | 5 3                          | 7 0                           |
| Victoria .....          | 2-16                          | 3-32                           | 3 8                          | 5 7                           |
| Western Australia ..... | 2-68                          | 3-54                           | 3 3                          | 4 1                           |

I understand that the warrantableness of some of the developmental expenditure incurred by the State within recent years has been questioned, and in particular expenditure incurred in the gradual development of Eyre Peninsula.

In the latter connection it is necessary to draw attention to the fact that 60 per cent. of the area of the State lies to the West of Port Augusta, including Eyre Peninsula and its Northern hinterland, and 40 per cent. only to the east of the Port, including the earlier settled portions of the State.

It seems to me unthinkable that any State could afford to leave idle more than 50 per cent. of its effective area, when it was known that a large proportion of this was suitable for Sheep or Wheat, upon which the Eastern portion of the State had been effectively settled. Attention should be drawn to the fact that the greater part of the Peninsula was covered with Mallee or low scrub and that the actual cost of clearing and development has fallen not upon the State, but upon the individual settler, and frequently to his eventual loss. Nor should it be forgotten that however good the quality of the soil, Mallee Blocks, reclaimed by individual settlers, cannot as a rule be expected to reach normal farming conditions until at least 10 years from date of original settlement. Unfortunately, Settlers have been faced by a series of unfavorable seasons since early settlement and the State has been compelled to supply them with special assistance to enable them to keep on the land. The position has been further complicated by the settlement of Returned Soldiers on the only available Crown Lands of the State, and many of them have unfortunately proved unsuitable settlers.

The main State developmental works are represented by a narrow gauge railway line and an attempt to provide water to the central areas from the Southern end of the Peninsula. The expenditure involved was inevitable if the Peninsula were to be settled, and in my opinion with the eyes of land-hungry neighbors upon our sparsely settled areas no State could afford not to attempt the settlement of more than one-half of its available area. It is probably true that public works on the Peninsula do not at present pay interest and are therefore a burden upon taxpayers of the eastern half of the State. But with a complete knowledge of the Peninsula and its conditions I am prepared to maintain that, given a fiscal policy more in keeping with the rural requirements of the Commonwealth than we have hitherto experienced, Eyre Peninsula should, in the course of time, be able to meet interest on any expenditure that may have been incurred on its behalf. I stated in evidence before an earlier Commission that between 1935 and 1940 the Peninsula should carry in the neighborhood of 1,500,000 acres of Wheat, from which 15,000,000 bush. might be expected, and that its flocks should expand to from 1,600,000 to 1,800,000 Sheep. To these opinions I still adhere, with the addition that the Dairying and Poultry Industries are also capable of important development over this area.

The costliness of the River Murray settlements has also been criticised, and in some directions perhaps not without reason. Mistakes have no doubt been made, but could it have been otherwise in a national undertaking of this magnitude? Two factors have added very considerably to the costs incurred, namely:—

- (1) the hurried settlement of numerous Returned Soldiers anxious to resume normal civil life, which for sentimental reasons could not have been avoided, and
- (2) direct and indirect influence of a high tariff policy.

I am of the opinion that in its attempts at settlement of Eyre Peninsula, and at development of the River Murray Irrigation areas, particularly in relation to the settlement of Returned Soldiers, South Australia has undertaken national work of major importance, and that considering that the policy that has led to the enrichment of the industrial States has led to corresponding impoverishment of South Australia, it seems reasonable that the Commonwealth as a whole should assist this State to carry a burden which unfortunately it is no longer able to bear without outside assistance.

It is often stated that the countryside benefits from economic association with large centres of population, and whilst from the general viewpoint this is undoubtedly true, it cannot be said to apply to the association of essentially rural communities, such as South and Western Australia, with distant urban centres, such as Sydney and Melbourne, the home territories of which are amply adequate for the supply of all requirements. Unfortunately, the collection of Interstate statistics on the subject has been abandoned since 1909, and it is no longer possible to set out the actual position on the basis of exact figures. From inquiries that I have made, however, it would appear that the value of our Interstate exports of Horticultural Produce for the 12 months ending on June 30th, 1930, did not exceed £170,000, and consisted chiefly of Oranges and Tomatoes consigned to the Melbourne Market. Our Wines and Brandies, on the other hand, have undoubtedly benefited from Federation, and now have an Interstate export trade of a yearly value varying from £500,000 to £750,000. But this is a very small set-off to the value of the manufactured articles we are compelled by High Tariffs to receive from the industrialised States. Moreover, notwithstanding the federal agreement, the course of Interstate trading is not all plain sailing; witness the uncomfortable position of South Australian Exporters of Eggs on the Sydney market, where special measures appear to have been taken to prevent them poaching on local preserves.

The Federal disabilities under which South Australia appears to me to labor may be summarised as follows:—

1. Natural conditions have made of South Australia an essentially rural State, and unfortunately she has been unequally yoked in a federation with two large States which have gradually expanded upon industrial lines.

2. Federation has checked the development of local industries, and in some cases obliterated them. It has raised the cost of necessities of life and industry, with corresponding increase in costs of rural production, upon which our economic life is wholly dependent. Natural conditions compel us to sell in the cheapest markets and artificial ones to buy in the dearest.

3. And to-day South Australia finds it almost impossible to market surplus agricultural produce overseas at a profit to producers and to the State.

4. The practical disappearance of taxable industrial wealth from the State has thrown the burden of taxation upon rural production and impoverished the State and its main producers.

5. Even as a rural State, South Australia suffers in comparison with its better endowed neighbors. Over 81 per cent. of its territory lies outside the 10in. rainfall line and no more than 6.4 per cent. of its total territory is suitable for agricultural operations. Moreover, the major portion of the land in cultivation is "Mallee" land, and therefore of relatively low natural fertility.

6. The absence of good underground water supplies has rendered necessary costly artificial supplies for both town and country, and has helped to inflate costs of rural production, both directly and indirectly.

7. Closer settlement has been hampered by Federal Fiscal Policy, with the result that we have been thrown back upon extensive farming and the normally low returns per acre which characterise this type of farming.

8. Forty per cent. of the territory of South Australia is carrying the burden of three national undertakings of major importance, in which the Commonwealth is intimately concerned, namely:—

(a) the development of Eyre Peninsula, which may eventually claim the position of a separate State.

(b) the opening up of the River Murray Irrigation Areas, and

(c) the settlement of Returned Soldiers.

9. The limits of local taxation appear to have been reached, if not over-stepped, and to remedy the position in which we find ourselves, I know of no alternative but—

(a) a radical change in Federal Fiscal Policy towards low tariffs for revenue only.

(b) substantial Federal grants enabling the State Government gradually to reduce local taxation, which eventually would be reflected in lower cost of rural production.

(c) Secession which would restore to us our liberty of action and enable us to work out our destinies on our own lines.

I recognise that in ordinary circumstances my statement of our disabilities should end here, and that any addendum would be in the nature of an anti-climax. Quite recently, however, I happened to come across an article in the *Nineteenth Century Magazine* entitled "A Policy for Central Europe." The article, which is by a former Minister of Agriculture of Czechoslovakia, is a reply to the suggestion that Europe should adopt a Federal Tariff Union. The position as pictured by Doctor Milan Hodza is so similar to our own that I take the liberty of adding a few extracts as an appendix to my personal statement:—

If we imagine Pan-Europe as a Confederation with the tariff barriers raised, as a unitary customs area, then it is clear that Pan-Europe is not possible, and, even were it possible, that it could not be advantageous, and therefore not permanent. Europe is not an economic unity. West-Europe, predominantly industrial, has other economic interests than the agrarian States of Central Europe. West-Europe has a surplus output of industrial products, we have a surplus output of agricultural products, and therefore we must make a distinction between what would benefit the international Capital invested in West-European industry and what the farmer in Central Europe urgently needs. . . .

"If Pan-Europe were to arise suddenly, sweeping away all the Tariff barriers, including the agricultural, we should be overwhelmed by the economic and financial power of West-European Industry. We should have all the disadvantages of a great customs area dominated by industry, and we should have neither the strength to resist nor the guarantee of an economic safeguard for agriculture. That would mean the pauperisation of agrarian States of Central Europe and the pauperisation of agrarian democracy itself. If the farmers of these States cannot safeguard their products, and the State cannot safeguard its small peasant landholders, that would mean that agrarian democracy would be shaken to its foundations in Central Europe, since the agrarian represents the only stable element. It would mean that the ground was cut away from under the feet of cultural development in Central Europe. We should be threatened by the danger of chaos which is to-day, in the neighborhood of Soviet Russia, altogether unthinkable.

"That would be the effect of Pan-Europe as it is at present conceived organised from the standpoint of West-European capitalism and industrialism. It is for this reason that we must approach the question of international 'rapprochement' by progressing from the smaller problems to the greater, and not *vice versa*. Only in this way can Pan-Europe be made a reality, resting not on public manifestations of international enthusiasm, but on a real abolition of the economic friction between the different States."

There, it seems to me, speaks a man of far greater vision than the South and West Australian protagonists of Federation in the last century. We accepted federation and unified customs without taking thought of our special agricultural interests, and now we are suffering for the lack of thought of the Fathers of Federation and the "public manifestations" of federal "enthusiasm." It is much to be hoped that in common fairness, future generations will not be permanently penalised for the hastiness and lack of foresight of their predecessors.

## REPORT ON PIG FEEDING EXPERIMENTS AT ROSE-WORTHY AGRICULTURAL COLLEGE.

[By W. R. BIRKS, B.Sc., Agric., Principal, and S. E. WHICKER, D.D.A.,  
Livestock Assistant.]

A further pig feeding test was carried out in the College piggery during the Spring of 1930, with the following main objectives in view:—

1. To test the effects of the addition of a complex mineral mixture to the normal ration.
2. To compare the relative effects of superphosphate in this mineral mixture with those of the chemically less active phosphatic materials, bonemeal, and ground rock phosphate.
3. To compare the efficacy of a mixed grain ration with that of a single grain ration (viz., barley).
4. To test the effects, economic and other, of allowing an unlimited food supply in self-feeders on the "free choice" principle.

For the purpose of the experiment eight pens of four pigs each—pure Berkshires—were employed. The ages of these pigs at the commencement of the test ranged from 19 weeks to 26 weeks and their live weights from 54lbs. to 148lbs. Seven pens were housed in a rank of similar sties, built of cement concrete, measuring 8ft. by 16ft., half

The Open Yard in which Pigs of Pen No. 8 were Run.

covered in, and with the covered part floored with hardwood. All ordinary precautions, as to sanitation, the control of vermin, &c., were observed. Pigs of the eighth pen were run in a yard measuring 150ft. by 27ft., in which there was an ample supply of natural grazing.

The ration adopted as standard for this test (largely as a result of previous tests) was made up of the following constituents in the proportions shown:—Crushed barley 8, Crushed Wheat 4, Crushed Peas 2, Meatmeal 1, and green feed equivalent to approximately four parts of dry matter. This is referred to below as the “standard ration,” and in those pens which were given a limited supply of food it was fed at the rate of approximately 4½lbs. per day per 100lbs. live weight of the pigs.

The mineral mixture consisted of Charcoal 20 per cent., Salt 20 per cent., Sulphate of Iron 5 per cent., Epsom Salts 5 per cent., Sulphur 5 per cent., Bicarbonate of Soda 5 per cent., Potassium Iodide ½ per cent., and Bonemeal, Superphosphate or Ground Rock Phosphate 40 per cent. This mixture was added at the rate of 3lbs. per 100 of the grain ration. In the “free choice” pens the various grain constituents of the “standard ration” (and the mineral mixture where given) were placed in separate hoppers of wooden self-feeders, which were replenished frequently so that all the foodstuffs were available to the pigs continuously.

The details of the feeding of the eight pens are given below.

TABLE I.—*Showing the Diet Supplied to Eight Pens of Pigs under Test.*

| Pen No. | Diet.                                                                                                                                  |
|---------|----------------------------------------------------------------------------------------------------------------------------------------|
| 1       | Standard ration (without mineral mixture).                                                                                             |
| 2       | Standard ration, mineral mixture, Superphosphate.                                                                                      |
| 3       | Standard ration, mineral mixture, Rock Phosphate.                                                                                      |
| 4       | Standard ration, mineral mixture, Bonemeal.                                                                                            |
| 5       | Barley, mineral mixture, Bonemeal.                                                                                                     |
| 6       | Free choice, standard ration constituents (without mineral mixture).                                                                   |
| 7       | Free choice, standard ration constituents Bonemeal mineral mixture (also as “free choice”).                                            |
| 8       | Free choice standard ration constituents, Bonemeal mineral mixture (also as “free choice”), and open grazing in lieu of cut greenfeed. |

From the commencement of the test the pigs in the free choice pens obviously did better than the others, and their average consumption of food was approximately 30 per cent. more. The rate of increase was eventually much greater in these pens than in the others, and these pigs were over fat before the others had reached bacon weight (170lbs. live). At the third weighing, i.e., six weeks from the commencement of the test, the mean weights in the free choice pens were all in excess of 170lbs., and for the purpose of this report the experiment is terminated at that point. The relative rate of fattening increase in each pen is shown in the table below.

TABLE II.—*Relative Rates of Fattening Increase of Pigs Variously Fed over a Period of 42 days.*

| Pen No. | Mean Initial Weight. | Mean Initial Age. | Mean Final Weight. | Highest Individual Fortnightly Gain. | Average Daily Gain in Weight per Pig. |
|---------|----------------------|-------------------|--------------------|--------------------------------------|---------------------------------------|
|         | Lbs.                 | Days.             | Lbs.               | Lbs.                                 | Lbs.                                  |
| 1 ..... | 69.50                | 132               | 135.5              | 28                                   | 1.57                                  |
| 2 ..... | 92.50                | 160               | 167.75             | 31                                   | 1.79                                  |
| 3 ..... | 84.50                | 142               | 151.5              | 35                                   | 1.60                                  |
| 4 ..... | 87.75                | 150               | 155.75             | 30                                   | 1.62                                  |
| 5 ..... | 102.75               | 175               | 165.25             | 28                                   | 1.49                                  |
| 6 ..... | 100.75               | 151               | 184.75             | 38                                   | 2.00                                  |
| 7 ..... | 102.75               | 149               | 193.50             | 36                                   | 2.16                                  |
| 8 ..... | 113.75               | 182               | 189.0              | 32                                   | 1.79                                  |

From the above it will be seen that pens receiving the mineral in their grain ration (Nos. 2, 3, and 4) have each shown a more rapid rate of increase than in that deprived of minerals (No. 1).

Similarly, in the free choice pens, No. 7, with access to the mineral mixture, shows a slightly higher rate of increase than No. 6 without minerals.

The differences are small, but the effects might have been more marked if the pigs had come to the test with a low mineral reserve. As a matter of fact, they had previously been fed on a ration containing a full supply of minerals, and deprivation of this supply might have taken a longer period than was covered by the test to produce its full effect.

With regard to the relative effects of superphosphate, ground rock phosphate, and bonemeal (pens 2, 3, and 4 respectively), it will be seen that the pigs receiving superphosphate made a definitely more rapid increase by approximately 11 per cent. It can at least be said then that the superphosphate had no ill-effect, and as it is decidedly cheaper than bonemeal, it can apparently be definitely recommended for incorporation in mineral mixture for pigs.

The Type of Self-feeder used in Pens Nos. 6, 7, and 8.

The single grain ration, barley, in Pen No. 5, gave the lowest rate of fattening increase recorded, 1.49lbs. per day, as against 1.62 in No. 4, the pen receiving mixed grains, but otherwise similarly treated.

In the free choice pens, Nos. 6, 7, and 8, very rapid increases in weight were recorded, averaging approximately 2lbs. per pig per day.

An interesting feature of this test was the marked preference for wheat shown by these pigs. The total quantities of each constituent of the diet taken by each pen are shown in the table below.

TABLE III.—*Showing the Relative Proportions in which Various Constituents of the Diet were Selected by Pigs Fed on the "Free Choice" System.*

| Pen No. | Wheat. | Barley. | Pease. | Meat Meal. | Mineral Mixture. | Greenfeed (equivalent dry matter). | Total. |
|---------|--------|---------|--------|------------|------------------|------------------------------------|--------|
|         | Lbs.   | Lbs.    | Lbs.   | Lbs.       | Lbs.             | Lbs.                               | Lbs.   |
| 6       | 957    | 43      | 64     | 28         | —                | 70                                 | 1,162  |
| 7       | 1,034  | 22      | 180    | 45         | 5                | 70                                 | 1,336  |
| 8       | 875    | 144     | 101    | 9          | 15               | (grazing)                          | 1,144  |

The mean total quantity of food consumed by each pig was 304lbs., whereas each pig of similar weight in the pens receiving a limited ration consumed 231lbs.

A further point of interest shown in the above table is the very low consumption of minerals in both pens which had access to the mixture. This again may be due to the fact, referred to above, that the pigs came to the experiment well provided with minerals from their previous feeding.

Turning now to the economic aspects of the test, calculations have been made of the mean quantities of food consumed in each pen per pound of increase in live weight and the cost of these foodstuffs. These details are shown in the next table. For the purpose of these calculations the following values have been assumed:—Wheat 3s. per bushel, barley 2s. per bushel, pease 5s. per bushel, meat meal 2d. per lb., mineral mixture: bonemeal 11s. 9d. per 100lbs., superphosphate and rock phosphate 8s. 5d. per 100lbs, green feed 10s. per ton, or 30s. per ton of equivalent dry matter.

TABLE IV.—*Showing Mean Daily Consumption of Foodstuffs and Mean Cost per Pound of Increase in Liveweight in Pigs variously Fed.*

| Pen.                                                                                  | Average Daily Increase in Live-weight. Lbs. | Mean                                              | Mean Cost of Food per Pound. Pence. | Mean Lbs. of Food to 1lb. of Gain. Lbs. | Mean Cost per Lb. of Increase. Pence. |
|---------------------------------------------------------------------------------------|---------------------------------------------|---------------------------------------------------|-------------------------------------|-----------------------------------------|---------------------------------------|
|                                                                                       |                                             | Daily Food Consumption per Pig (Dry Matter). Lbs. |                                     |                                         |                                       |

| 7. Free Choice Standard Ration Constituents, Bone-meal Mineral Mixture .....          | 2.16                                        | 8.07                                              | .678                                | 3.74                                    | 2.53                                  |
| 8. Free Choice Standard Ration Constituents (open grazing). Bone-meal Mineral Mixture | 1.79                                        | 7.24                                              | .614                                | 4.03                                    | 2.47                                  |
| Means .....                                                                           | 1.75                                        | 6.30                                              | .615                                | 3.59                                    | 2.20                                  |

It will be seen that Pen No. 7, which showed the most rapid increase in live weight, also shows the highest cost of production. The rate of feeding, viz., 8lbs. per day per pig of an average weight of approximately 145lbs. over the whole test, may therefore be regarded as somewhat excessive.

On the other hand, Pen No. 6, with an increased daily consumption of food of over 1lb. per pig per day as compared with Pens Nos. 3 and 4, shows a lower cost of production per pound increase.

Pens Nos. 1 and 5, which show the lowest rates of increase, show also the lowest production costs. This, in the case of Pen No. 5, is, of course, due to the relatively low cost of barley, and in Pen No. 1 the result may have been influenced by the relatively younger age and lower weight of the pigs in this pen. This was an unfortunate discrepancy which seemed inevitable at the time, but resulted in this pen requiring a smaller ration. The pigs were also, no doubt, at a more suitable age than the others for rapid fattening.

The actual results of this test, however, appear to show that:—

1. The feeding of a complex rich diet (as compared with a single grain ration) well provided with minerals, and
2. The supply of an unlimited amount of food,

have each, in turn, been factors in increasing the cost per pound of increase in live weight. This increase in cost, however, is probably offset to some extent by the rapidity of fattening, and it has been shown that mean increases of approximately 2lbs. per pig per day may be achieved by the intensive methods of feeding employed.

Assuming that the normal fattening process for bacon pigs consists of increasing the live weight from 50lbs. to 170lbs., the time required for this, at a rate of 1½lbs. per day, is 80 days, while at 2lbs. per day it is 60 days, and the increased cost (comparing Pens Nos. 5 and 6) is approximately 2s. 6d. per pig. Or, basing calculations upon a comparison of the results in Pens Nos. 2 and 5, a saving of a fortnight in the assumed normal fattening process might be expected at an extra cost of 1s. 1d. per pig.

The shortening of the fattening period represents a quicker turnover and a reduction in general risks, but the value of these advantages depends upon the circumstances in any particular case.

Further, comparing Pens Nos. 5 and 8, the additional cost of 5s. 7d. per pig for food in No. 8 is offset by a fortnight's less fattening time, a reduction in labor for attention by cleaning out once in week in No. 8 as compared with daily cleaning in No. 5, and feeding three times a week instead of twice daily. The labor of cutting and carting green feed is also eliminated and the initial outlay for buildings is less when pigs are run in the open.

#### SUMMARY.

In so far as definite results may be derived from a single test of this sort they appear to be as follows:—

1. Feeding pigs on a rich mixed diet, as indicated above, at the rate of 4½lbs. per day per 100lbs. live weight, with a suitable mineral mixture containing superphosphate and other ingredients as shown in the text may be expected to result in daily increases of up to 1½lbs. per pig per day.
2. The rate of fattening may be increased to 2lbs. per pig per day by supplying 5lbs. to 5½lbs. of food per 100lbs. live weight.
3. The mean rate of consumption of food per pound increase in live weight has been approximately 3½lbs. and the mean cost of producing a gain of 1lb. live weight has been 2½d. on the scale of prices indicated in the text.
4. The addition of the more expensive ingredients of the ration, such as pease and meat meal and the increased rate of feeding have together increased the cost of food by from ½d. to ¾d. per lb. of increase in live weight, but have reduced the time required for fattening by from 16 per cent. to 25 per cent.
5. The system of "free choice" feeding on green pasture, though slightly more expensive so far as food costs are concerned, has a good deal to recommend it, having regard to the quick fattening and the reduction in labor costs and the more simple equipment of building required.
6. Finally, bearing in mind the preferences indicated by the pigs in the free choice pens and the current trend in grain prices, an economical ration for pigs at the present time appears to be a dry crushed mixture of grains in the following proportions:—

|              |         |
|--------------|---------|
| Wheat .. ..  | 5 parts |
| Barley .. .. | 4 parts |
| Pease .. ..  | 1 part  |

Meat meal should be added (in the absence of skim milk) at the rate of 4 parts per 100 of the above mixture and a superphosphate mineral mixture (such as that indicated above) at the rate of 1½lbs. per 100, together with whatever green feed may be available.

#### ERADICATION OF YACCA.

Referring to the experiments with the eradication of Yacca, reported in the January issue, Mr. R. Hill states that on page 635 of that issue the quantities should be 1½ tins instead of 1½galls., as quoted.

## INSECTS OBSERVED ON CROPS IN SOUTH AUSTRALIA DURING PERIOD JUNE, 1928, TO JUNE, 1930.

[By J. DAVIDSON, D.Sc., F.E.S., Waite Agricultural Research Institute,  
University of Adelaide.]

The following observations on insects found associated with agricultural and horticultural crops in South Australia form the first of a series of records which will be published annually or biennially in future years. With the present list it is not intended to include all the species known to be harmful to crops in the State. The definite determination of the species concerned has not been possible in some cases and such records are omitted. Additions will be given in later reports.

It is hoped that in this way a complete record of the occurrence of insect pests of crops in the State eventually will be obtained. The value of the records will depend upon adequate systematic observations being made, so that after a lapse of years the occurrence of important pests during different periods will be available for comparison. With the active co-operation of the officers of the Department of Agriculture such records are assured and valuable data will be accumulated. The relationship between weather conditions and outbreaks of insect pests is a question of great importance in agricultural entomology and systematic records over a series of years are necessary before any serious attempt can be made to interpret this relationship. Detailed records of the behavior of the more important insect pests from year to year will yield important information regarding the distribution and seasonal prevalence of these insects.

The recorded notes on the different species are necessarily brief in the present summary. Modifications may be made in later reports so as to include new observations of interest to growers and any special new features regarding control measures. It is felt, however, that it is best to defer this until a more complete list of the economic insects of the State has been obtained.

Owing to climatic differences in various regions of the State, chiefly due to altitude and rainfall, it is considered desirable to make references in many cases to the particular districts to which the records refer. In the case of horticultural crops the seven districts referred to in the annual report of the Chief Horticultural Instructor, dated October 16th, 1929, and September 26th, 1930, are used for convenience.

Sincere thanks are due to the Director and staff of the Department of Agriculture for the helpful assistance they have afforded me in many ways. The active interest taken in the matter by Mr. G. Quinn, Chief Horticultural Instructor, and his field officers has been invaluable. The observations on insect pests contained in the periodical reports of the horticultural instructors in the various districts have formed the basis of the present survey.

Thanks are also due to Mr. A. M. Lea, Entomologist at the Adelaide Museum, for his unfailing courtesy and assistance in identification of specimens.

### I. CEREAL CROPS.

"White grubs" (*Scarabaeidae*) caused damage in small areas to oats and barley in Yorke Peninsula during spring of 1929. (See Davidson, J., *Journ. Agric.*, South Australia, 1930, vol. 34, p. 224).

The weevil (*Polyphrades lactus* Black.) was recorded as feeding on wheat plants in the Talia district in September, 1929.

The oat eelworm (*Heterodera schachtii* Schm.) occurred on roots of wheat, oats, and barley in several districts during the winter months in both years. These nematodes cause an abnormal development of the roots, particularly of young plants, growth being checked. (See J. Davidson, 1930, *Journ. Agric.*, South Australia, vol. 34, 278-285, and A. R. Hickinbotham, vol. 34, 386-392).

## II. PASTURE AND FORAGE CROPS.

The clover springtail or lucerne flea (*Sminthurus viridis* Linn.) is a serious pest of lucerne on the irrigation flats in the Murray Bridge district during May to October. It also occurs widely throughout the better rainfall areas of the State, especially on Subterranean clover (*Trifolium subterraneum*) and lucerne. It is also common on many garden plants and weeds, particularly the introduced Cape weed (*Cryptostemma calendulaceum*). "White grubs" were prevalent in pasture areas in the South-East during spring of 1928 and 1929. The boll worm (*Heliothis obsoleta* Fabr.) occurred on lucerne in early summer in 1929 and 1930 in Mid-northern districts. (See paper by A. M. Lea, *Journ. Agric.*, South Australia, 1928, vol. 31, pp. 608-615). The blue Lycaenid butterfly (*Zizania labradus* Godart) was present in large numbers in lucerne areas at Booborowie (Mid-northern district) during February, 1930. In some cases the larvae had eaten into the base at the flowers, which consequently failed to set seed pods.

The red-legged earthmite (*Penthalcus destructor* Jack) was present in the Riverton district in a local garden in July, 1928 and 1929, but did not occur in a serious epidemic form. It occurs in other areas of the State. (See W. C. Johnston, *Journ. Agric.*, South Australia, 1930, vol. 34, p. 283). The correct name of this pest is stated to be *Halodystaeus destructor* Tucker. (See *Journ. Comm. Council Sci. Ind. Res.*, 1930, vol. 3, p. 190.

## III. FIELD AND MARKET GARDEN CROPS.

The potato moth (*Plutomaea operculella* Zeller) was active in Mount Gambier area and Glencoe during March and April, 1929, being also severe in Southern districts. Cut worms (*Agrotis munda* Walk.) caused damage to roots of strawberry plants in the Adelaide hills, and also "white grubs." Commercial naphthalene worked into the soil between the rows at the rate of 3ozs. per square yard gave relief. The cauliflower riddler (*Plutella maculipennis* Curt. (*P. cruciferarum* Zell.) caused damage to cabbage and cauliflower in Southern districts. The boll worm (*Heliothis obsoleta* Fabr.) occurred on tomatoes in the Mount Lofty district during November, 1928, and in Southern districts during March and November, the larvae eating into the fruit.

The tomato weevil (*Desiantha nociva* Lea.) occurred on tomatoes in Adelaide district during October and November, 1929, and the cockchafer beetle (*Isodon pecuarius*) was found eating tips of tomato plants at Port Pirie in October, 1929. The banded pumpkin beetle (*Aulacophora hilaris* Boisd.) was active in some gardens on the Adelaide plains in November, 1929. The black carnation thrip (*Frankliniella insularis* Franklin) occurs on tomato plants and on the flowers of many other plants during summer. (See J. Davidson and J. G. Bald, *Bull. Entom. Research*, 1930, vol. 21, pp. 365-385). This insect does not directly damage the tomato plant, but it has been shown under experimental conditions that the species can transmit spotted wilt disease of tomatoes, and is therefore to be considered as an important pest. (See G. Samuel, J. G. Bald, and H. A. Pittman, *Com. Council Sci. Ind. Res.*, 1930, *Bull. No. 44*). The mite (*Phyllocoptes lycopersici* Tryon) occurs on tomato plants, causing a brown discoloration of the stem and leaves. White fly (*Trialeurodes vaporariorum* Westwd.) was troublesome in tomato glasshouses in districts round Adelaide in both years.

*Aphides*.—The strawberry aphid (*Capitophorus fragariae* Theob.) was recorded from strawberries in the Mount Lofty district in March, 1929, but disappeared by the end of April. The parsnip aphid (*Cavariella pastinacae* Linn.) and also (*C. aegopodii* Scop.) were recorded from parsnips in the Mount Lofty area and on Adelaide plains during November and December, 1929. The green peach aphid (*Myzus persicae* Sulzer) occurred on cabbages, cauliflowers, and swedes in Southern districts and Adelaide plains, also on Mount Lofty ranges. The cabbage aphid (*Brevicoryne brassicae* Linn.) was also prevalent on cabbage in several districts. The black bean aphid (*A. rumicis* Linn.) occurred in November, 1929, in South-East and also Southern districts. A

subterranean aphid occurred in large numbers on rhubarb and roots of *Chenopodium* sp. in Basket Range in October, 1929. It appears to be the same as *Pemphigus betae* Doane or a closely allied species.

The bulb mite (*Rhizoglyphus hyacinthi* Banks) was found infesting bulbs in Mount Lofty district.

#### IV. FRUIT CROPS AND VINES.

Codlin moth (*Cydia pomonella* Linn.) was severe in some districts on apples during February and March, 1929. Observations on captures in bait traps by Mr. J. B. Harris in the Northern districts showed that the first big flight occurred in that district during first week in November, as was the case in the three previous years. There are two full broods and may be a partial third brood. Late attacks in March, 1929, were noted in some orchards in Southern districts. Pears were reported to be slightly attacked in some orchards in Adelaide plains and more severely in the Lower Murray Valley. A small attack on walnuts was recorded in the Southern district in March, 1929. Mr. R. Fowler (Bull. No. 243, Dept. Agric., S. Australia, 1930) has given the results of experimental tests carried out at the Blackwood Experimental Orchard.

The light brown apple moth (*Tortrix postvittana* Walk.) was present in normal numbers during November, 1929, in Northern and Central districts.

The boll worm (*Heliothis obsoleta* Fabr.) was found boring into young apples at Brighton at end of November, 1929, and also eating the tips of young shoots, doing considerable damage. Apricots and plums were similarly attacked.

The apricot borer (*Cryptophaga unipunctata* Donovan) was observed in November, 1929, in Southern districts. The vine moth (*Agarista glycome* Linn.) was prevalent in April, 1929, in South-Eastern district. The orange butterfly (*Papilio anactus* Macleay) occurred in fair numbers at Mypolonga during March, 1930.

The cherry and pear slug (*Caliroa cerasi* Linn.) was severe on pears in March and December, 1929, in Southern districts, and active on pear and hawthorn the following month on the Adelaide plains.

The apple root borer (*Leptops rhizophagus* Lea) has caused considerable damage in apple orchards in the Wirrabara district, and *L. robustus* Oliv. is present in some orchards in the Mount Lofty ranges.

The curculio beetle (*Otiorhynchus cribricollis* Gyll.), a general feeder on foliage and twigs of fruit trees, was much in evidence during March, 1929, in South-East, Central, and Southern districts. It caused much damage in the latter district in February, 1930. In December, 1929, an area of young vines near Adelaide was severely attacked. (See paper by A. M. Lea, *Journ. Agr.*, South Australia, 1927, vol. 30, pp. 582-598). A flight of cockchafers (*Heteronyx* sp.) occurred on an acre of two year old vines near Angaston in October, 1929, causing much damage. An outbreak of the bug (*Oxycarenus lactuosus* Mont. et Sign.) occurred at Greenock in January, 1929, the pest swarming over an area of young vines.

*Aphides*.—The green peach aphid (*Myzus persicae* Sulzer) was unusually severe in early summer of 1928 and caused much damage to peach, apricot, and nectarine trees. The damage was not so serious in 1929. This pest lives on a wide range of plants throughout the year, and only a few sexual forms have been observed on the orchard trees in the autumn. A few sexual females were found on peach trees at Blackwood State Orchard on May 8th, 1929, and stem females from the eggs were found about the middle of the following September. (See experiments by R. Fowler, *Journ. Agr.*, South Australia, 1930, vol. 34, pp. 62-63).

The black peach aphid (*Anuraphis persicae-niger* Smith) was particularly prevalent in some districts in 1928, but occurred only in normal numbers during 1929. The species is readily controlled with insecticides.

The pear root aphid (*Eriosoma lanuginosum* Htg.) caused the loss of some nursery pear stocks at Balhannah. It occurs on roots of established pear trees in some orchards in Adelaide hills. (See Davidson, J., *Journal of Agriculture*, South Australia

1929, vol. 32, p. 798). The woolly apple aphid (*Eriosoma lanigerum* Hausm.) is generally distributed. It was particularly noted in orchards in Mount Lofty ranges and Southern districts in March, 1929, and again during August to December, but was checked by heat in January. *Aphelinus mali* Hald., which has now been distributed to various districts from Blackwood Experimental Orchard chiefly through the active interest of Mr. R. Fowler, the Manager, is becoming established in certain districts. It is in evidence in orchards at Kangarilla, in the Coromandel Valley, and some orchards in the Adelaide hills. In April, 1929, it appeared to be established at Kybybolite.

The black cherry aphid (*Myzus cerasi* Fab.) was prevalent in the Millicent district in December, 1929, but the attack was checked by the heat in January.

The melon aphid (*Aphis gossypii* Glov.) occurred in numbers on apricots and nectarines in a garden at Brighton in December, 1929, being present also on a wide range of plants, including *Vicia calcarata*, *V. tetrasperma*, and Penstemons.

The orange aphid (*Aphis tavaresi* Del Guere) was noted in Southern districts in November, 1929. *Toxoptera aurantii* Koch. also occurred in small colonies on orange and lemon trees.

**Scale Insects (Coccidae).**—Scale insects on citrus, chiefly Red scale, are controlled by means of the efficient organisation of the Horticultural Department for fumigating infested areas. (See article by C. H. Beaumont, *Journ. Agric.*, South Australia, 1930, vol. 33, pp. 618-624).

The dark-brown olive scale (*Saissetia oleae* Bernard) was more prevalent than usual in 1929 on Adelaide plains. It was present to a less extent in Southern districts.

Red scale (*Chrysomphalus aurantii* Maskell) occurs in the Adelaide area. It was found in one orchard at Berri in September, 1929, and also noted on two properties at Renmark in April, 1930. The parasite *Aphelinus diaspidis* Howard was recorded as parasitising red scale freely in an orchard at Yankalilla in 1928.

The black scale (*Chrysomphalus rossi* Maskell) was noted on the lower Murray in July, 1929, and at Waikerie in May, 1930. In November, 1929, it occurred in Northern districts where it is not usually found.

The soft brown scale (*Lecanium hesperidum* Linn.) was noted on orange trees at Gawler in November, 1929. (See note in *Journ. Agr.*, South Australia, 1929, vol. 33, p. 328).

Mussel scale (*Lepidosaphes ulmi* Linn.) occurred on old apple trees in Mount Gambier district.

Red spider (*Tetranychus* sp.) and red mite (*Bryobia* sp.) caused damage in several districts, particularly on almonds, prunes, and plums.

The dried fruit moth *Plodia interpunctella* Hb. occurs as a serious pest of dried grapes after they are packed. (See J. G. Myers, Publication, Empire Marketing Board, No. 12, London, November, 1928, 36 pp.) The parasite *Habrobracon juglandis* Ashm. has been found associated with the pest attacking the larvae. (See H. Showell, *Journ. Agric.*, South Australia, 1928, vol. 31, pp. 1048-1056). *Ephestia cautella* Walk. has been observed in grape drying areas.

#### V. MISCELLANEOUS OBSERVATIONS.

Larvae of the sheep nostril fly (*Oestrus ovis* Linn.) were recorded from the heads of two wethers at Ramco in April, 1929.

The larvae of *Ohlenias pini* Tindale (Fam. Boarmidae) caused damage in plantations of *Pinus insignis* at Mount Burr in the South-East in the spring of 1928, but did not occur as a pest the following year. (See N. B. Tindale, Records of South Australian Museum, 1928, vol. 4, pp. 43-48.)

Outworms caused much damage to seedlings of *Pinus insignis* at Kuitpo Forest in October, 1928, the seedlings being eaten off at ground level. In December, 1929, older seedlings were also attacked at Happy Valley nursery, the tips of the plants being eaten off.

Larvae of the tiger moth (*Ardices gletigyni* Le Guil.) occurred in large numbers in spring of 1929 in Brighton area; they are destructive general feeders. The case moth (*Thyridopteryx herrichi* Westwd. caused much damage in a young plantation of *Eucalyptus gomphocephala* at Streaky Bay in March, 1929. The seedling gum moth (*Nola metallopa* Walk.) was very active on young gum trees in Adelaide foot hills. The larvae of a small moth (*Musotima ochropteralis* Guenee\*) caused serious damage to maiden-hair ferns in a small fern house near Adelaide. The caterpillars were present in large numbers, eating the foliage and rolling portions of the leaves in which they pupated. The borer (*Cryptophagus unipunctata* Donovan) caused damage to swamp oaks at Port Pirie. A number of larvae of the moth *Stericta costigeralis* Walk.\* were found on a dry broom fence at Murray Bridge on October 7th, 1929. They lived on this dry material in a cardboard box, eventually pupating in a silken case covering themselves with frass and pieces of dried plant. Two moths emerged on December 17th. Larvae found feeding on dried herbarium specimens at Murray Bridge High School proved to be the dried fruit moth (*Plodia interpunctella* Hub.), an unusual habitat for this moth.

The Cottony cushion scale (*Icerya purchasi* Maskell) occurred in Southern districts and in the Upper Murray district in July, 1929, but only in small colonies. The red bug (*Dindymus versicolor* H. Sch.) and the crusader bug (*Mictis profana* Fabr.) commonly occur on citrus trees, but no case of serious damage has been observed.

The green cockchafer (*Diplucephala colaspidoides* Gyll.) swarmed on young wattles in Southern districts in October, 1929. This species may on occasions attack fruit trees. Grubs of a weevil (*Balaninus* sp.) were found in a sample of acorns imported from Turkey for tanning purposes in March, 1929.

Two species of beetles (*Aphodius ambiguus* Boli and *Psummodius obscurior* Bl.) were received from Port Pirie district, it being stated they were damaging pea plants. This association, however, was doubtless only a chance one and they were not the cause of the damage. *Lagria grandis* Gyll. was common in the Southern districts. This species sometimes attacks soft fruits, but cannot be considered as a pest.

The longicorn (*Symphyletes deopiciens* Pasc.) was found affecting roses in the Brighton district in June, 1929, and also at Blackwood.

The stag beetle (*Lamprina* sp.) was observed eating leaves of apricot tree near Brighton in December, 1929.

A sporadic swarm of the minute Collembolan (*Proisotoma minuta* Schott.) occurred in a tomato glasshouse near Adelaide on June 26th, 1929. The insects congregated in depressions of the soil, forming masses about 4in. wide by ½in. to ¾in. deep. The species is stated to damage seedlings, but no damage could be ascribed to them on this occasion, and they disappeared after a few days.

## SUMMARY OF PLANT DISEASE RECORDS IN SOUTH AUSTRALIA FOR THE TWO YEARS ENDING JUNE 30TH, 1930.

[By G. SAMUEL, M.Sc., Waite Agricultural Research Institute, University of Adelaide.]

The rather dry conditions experienced during the two years did not favor the development of fungus diseases.

**CEREALS.**—There was very little loss from Take-all (*Ophiobolus graminis*) either year. Foot-rots caused by *Fusarium culmorum* and *Helminthosporium sativum* were determined, but were not widely distributed. Leaf Rust (*Puccinia triticina*) was rather prevalent, especially in 1928, but Stem Rust (*Puccinia graminis*) was of little importance, although slightly more prevalent than usual in 1928. Flag Smut (*Urocystis tritici*) is present annually in certain districts. Bunt (*Tilletia tritici*) was very scarce in 1928, but rather prevalent in 1929.

A seedling disease of wheat and oats (see *Journal of Agriculture*, S. Aus., 32, 40-43, three figs. (1928)), apparently caused by a species of *Rhizoctonia*, was determined from several localities in the mallee districts. The disease usually occurs only in small patches, in which the seedlings are stunted and later die.

Manganese deficiency disease of oats and barley seems to be somewhat more severe in dry seasons than in wet, on the special types of soil on which it has been found to occur.

**FIELD CROPS.**—Peas, grown in rotation with wheat, suffer in some localities from a collar rot due to an undetermined fungus. Downy Mildew of peas (*Peronospora viciae*), and of lucerne (*Peronospora trifoliorum*) were recorded for the first time, and also a wilt of lucerne due to *Sclerotinia* sp.

**TOMATOES.**—Spotted wilt (virus) was very prevalent in outdoor crops in 1928-9, but less so in 1929-30. In many cases it has caused considerable losses of young seedlings in glasshouses also. Streak (virus), and root-rots, in which *Verticillium albo-atrum* and *Colletotrichum atramentarium* appear to be the most important fungi concerned, are present every year in a proportion of the glasshouse. Early Blight of the leaves (*Macrosporium solani*) and a leaf blight apparently caused by a species of *Pleospora* very closely related to, if not identical with, *Pleospora herbarum*, were noted in a few cases.

A browning of leaves and stems due to a surface-feeding mite (*Phyllocoptes lycoopersici*) was also noted, both on outdoor crops and in glasshouses, but was not general.

**VEGETABLES.**—Turnip mosaic and pink root of onions were present in certain districts. Silver Scurf of potatoes (*Spondylocladium atrovirens*), Downy Mildew of lettuce (*Bremia lactucae*), Leaf blight of carrot seedlings (*Macrosporium carotae*), a *Botrytis* neck-rot of onions, and a bacterial spot of beans, probably due to *Phytomonas medicaginis*, var. *phaseolicola*, were recorded for the first time.

**FRUIT AND VINES.**—A number of cases of injury among vines and fruit trees, especially stone fruits and citrus, occurred during the last two years as a result of increase in the salt concentration in the soil following the run of dry seasons experienced lately. Powdery Mildew (*Sphaerotheca pannosa*) was noted for the first time, causing a mildew of apricot and peach fruits in two cases on single trees. Black Rot (*Physalospora cydoniae*) caused severe limb cankers on apples in one orchard. Downy Mildew of vines (*Plasmopara viticola*), which was recorded some years ago, has not been seen during the last three years. A case of Scaly Bark (*Peorosis*) of citrus was recorded for the first time.

**ORNAMENTAL PLANTS.**—A yellows disease of Iceland poppies (virus) was fairly prevalent in suburban gardens. Shot hole of Antirrhinum (*Heteropatella antirrhini*, conidial stage), a leaf spot of linden (*Gloeosporium tiliae*) and a powdery mildew (*Oidium*) on nursery stock of *Eucalyptus cornuta* were noted for the first time.

## POSSIBILITIES OF THE POULTRY INDUSTRY.

[By C. F. ANDERSON, Government Poultry Expert.]

The production of poultry and eggs is, at the present time, showing rapid expansion. For a number of years persons engaged in this form of production were rather scorned at, but during the last ten years the poultry industry has gradually forged its way to the front, until to-day it is an industry that lends itself particularly to great expansion, especially in view of the present values of wheat and its by-products.

When it is understood that the Australian, and particularly the South Australian, White Leghorn is pre-eminent in the world as an egg-producer, it can readily be seen what a wonderful asset the fowl is to South Australia, and the opportunity it offers for future expansion. Our somewhat despised White Leghorn hen of an average weight of 4lbs. produces on the average of 14 dozen eggs a year, equivalent in weight of 21lbs., or, in other words, she produces five-times her own weight in eggs.

In stressing the possibilities of the poultry industry, figures supplied by the Government Statistician for the year ending June, 1930, show that the value of the industry to South Australia on present-day values is £950,542, and the total numbers of poultry, ducks, geese, and turkeys existent in the State as on June 30th, 1930, were as follows:—

|                   |           |
|-------------------|-----------|
| Fowls . . . . .   | 1,552,760 |
| Ducks . . . . .   | 50,102    |
| Geese . . . . .   | 16,555    |
| Turkeys . . . . . | 46,401    |

or, a total of . . . . . 1,665,818 head

These figures offer more room for thought in the direction of the food consumed, and which is produced in our own State. It can be taken as a reasonable basis that each head of poultry, ducks, geese, turkeys, &c., consume 4ozs. of wheat per day per bird—whether in the form of wheat, or its by-products of bran and pollard—equivalent to approximately 2,500,000bush. of wheat per year.

During the present times, business men are naturally looking for primary production which is going to bring the most finance into the country, and it is in this direction that poultry production is eminently suited. Taking the average price of wheat to-day on the farm at 2s. per bushel—a very liberal estimate—has it ever occurred to commercial men that the conversion of this wheat into eggs would return 10s. per bushel? This estimate has been arrived at from long practical experience as a poultryman and as one who has been actively connected with the marketing of eggs. The average consumption of wheat per fowl can be taken as 1½bush. per year, equivalent at present-day values to 3s. The average production of a flock of high class White Leghorns can be put down at 12 dozen eggs per year, and taking present-day value of this class of egg at 10d. per dozen—which is a very conservative estimate—this production is equivalent to a return of 10s. for each 3s. worth of wheat fed to the fowl. These figures should give thought for serious consideration. I know that in past years the poultry industry has been to a certain extent “looked down on,” but, personally, I have never wavered in my opinion that our poultry industry is destined to be one of our greatest primary industries.

In support of this conclusion, I draw attention to the rapid growth of the exports of eggs overseas. Any advancement in our primary industries is usually judged by our exports, and in this direction the poultry industry compares more than favorably with any other line of primary production. Five years ago the exports of eggs from Australia were practically negligible. For the past season, concluded in December of last year, nearly 200,000 cases of eggs—each containing 30 dozen—were shipped from Australia. South Australia's share of this total was 25,000 cases, which was just double the quantity of eggs shipped in the previous year—which was then a record year. In other words, our previous record exports were doubled in one season. If our other primary industries had made similar advancement to that made by the poultry industry during recent years, we would not find ourselves in our present unfortunate position. The 25,000 cases of eggs exported from South Australia during the season just concluded were valued at £50,000, and the total exports of eggs from Australia for a similar period were valued at £430,000.

In addition to the overseas exports, South Australia is a large exporter of both eggs in the shell and egg pulp to the eastern States, the value of which is estimated at £150,000 per year.

With regard to the production of poultry and eggs, either as a side line or solely as a means of livelihood, South Australia is fortunately situated. We have one of the finest climates in the world, both for the rearing and production of poultry; our utility strains of poultry are unequalled in any country; we have all the necessary foodstuffs practically at our door; it is not necessary for one penny to go out of the State either for plant, equipment, stock, or food, and above all other considerations, we have a payable export Empire trade for all the eggs we are likely to produce in this country for generations to follow.

## ROSEWORTHY AGRICULTURAL COLLEGE.

## HARVEST REPORT, 1930-31.

[By W. R. BIRKS, B.Sc. (Agric.), Principal; T. A. COLE, D.D.A., Experimentalist; and L. W. BEAUMONT, R.D.A., Farm Superintendent.]

The season under review is the fourth in succession in which drought conditions have prevailed more or less. After the previous dry years and with practically no effective rains early in this season, it seemed reasonable to anticipate a break in the run of unfavorable conditions and a larger area than usual was sown. The rainfall for the year, however, amounted to only 12.85in., or 4.80in. below normal; only three other seasons since 1904 have been drier, viz., those of 1914, 1918, and 1919. The useful rain was 11.77in., and in the period referred to there have been seven seasons with less. The worst feature of the distribution of this season's rainfall, however, was the light and scattered nature of the September falls, which amounted to less than half the normal. Ultimately about a quarter of the area sown failed, or at least gave yields which, even in the past, have been regarded as unremunerative, and all average crop returns were below normal. Nevertheless, on certain areas of well worked fallow quite satisfactory yields were recorded—up to approximately nine bags of wheat, 12 bags of oats, and 2½ tons of hay per acre. In the aggregate, too, the grain yield of 3,267 bags in all, hay return 180 tons, and ensilage 286 tons, together represent the best harvest which has been taken from the College farm since 1925.

In the table below are shown the figures summarising the gross returns for the year and those giving the comparison between this year's average yields and the means of previous years:—

TABLE I.—*Showing Crop Returns for 1930 and Average Yields per Acre in Comparison with Mean Yields.*

| Crop.          | 1930 Harvest. |                  | Mean Yields. |            |
|----------------|---------------|------------------|--------------|------------|
|                | Total Yield.  | Average Yield.   | Period.      | Bush. Lbs. |
| Wheat .....    | Bush. 4,718   | Bush. Lbs. 15 24 | 1904-30      | 17 1       |
| Oats .....     | 3,757         | 16 26            | 1905-30      | 23 6       |
| Barley .....   | 969           | 16 48            | 1904-30      | 24 38      |

## WEATHER AND RAINFALL.

The first half of the year was practically devoid of useful rain. Until towards the end of June there had occurred only two rains which were, at all useful for germinating either weeds or crop. By that time all seeding, with the exception of the major part of the wheat, was completed. Some of the crops were therefore infested with weeds and were further handicapped by the slow start. Oats, which germinated in the last week in April, remained practically stationary in growth for two months. Germination in the early sown crops was irregular and what growth occurred was stunted owing to the dry cold conditions of June. Twelve frosts were recorded in that month, while the rainfall for the half-year had been 2½in. as compared with the normal—7½in.

July, on the other hand, was wetter than usual, free from frost, and provided unusually favorable conditions for growth. These conditions persisted for the first three weeks of August. All crops made rapid headway, and a bounteous harvest seemed assured if subsequent rainfall had been but normal. From August 22nd, however, there followed a period of seven weeks, during which showers were frequent, but almost all too light to be of any service to the crops which "went back" rapidly, especially those sown on stubble land. It was not until the fourth week of October that definite relief came in falls totalling 2½ in. of rain. By this time some 200 acres of the oat crops sown on stubble land had ripened off prematurely and may be regarded as having failed. All crops on fallow were, however, enabled to mature, and about half the area sown still seemed capable of returning much above average yields. Two further setbacks occurred, however, in November. On the 3rd and 4th the worst of a series of gales occurred. This did serious damage to the ripening oats and barley, which suffered to the extent of 10 bush. per acre, or more in some cases. The wheat, being later, escaped the thrashing effects of the gales, but as no further rain of importance occurred during November the heads did not fill out normally, and the grain was more or less shrivelled and yields reduced in consequence. This effect was accentuated to a certain extent by light attacks of rust, favored by the frequent showers throughout the spring.

Finally, weather conditions for harvesting were favorable, with one short break early in December, and the crops were taken off without serious interruption or further loss.

The details of weather conditions and rainfall are shown in the tables below, together with certain records of previous seasons:—

TABLE II.—*Showing the Annual Rainfall at Roseworthy College, together with the "Useful Rainfall" and the Percentage of "Useful" to Total Rainfall, the Total "Fallow Rainfall," and the Means for the Seasons 1904-30.*

| Year.       | Total Rainfall. | "Useful" Rain,<br>April 1st to<br>November 30th. | Percentage<br>"Useful" to<br>Total Rain. | Fallow Rain,<br>Previous<br>August 1st<br>to<br>March 31st. |
|-------------|-----------------|--------------------------------------------------|------------------------------------------|-------------------------------------------------------------|
|             | In.             | In.                                              | %                                        | In.                                                         |
| 1904 .....  | 14.70           | 11.60                                            | 79                                       | 11.16                                                       |
| 1905 .....  | 16.71           | 14.23                                            | 85                                       | 7.18                                                        |
| 1906 .....  | 19.73           | 16.31                                            | 83                                       | 7.96                                                        |
| 1907 .....  | 15.13           | 13.96                                            | 92                                       | 11.29                                                       |
| 1908 .....  | 17.75           | 15.52                                            | 87                                       | 9.13                                                        |
| 1909 .....  | 24.05           | 21.15                                            | 88                                       | 9.51                                                        |
| 1910 .....  | 23.87           | 16.79                                            | 70                                       | 17.56                                                       |
| 1911 .....  | 13.68           | 9.45                                             | 69                                       | 11.41                                                       |

## DIARY NOTES.

Approximately 500 acres of fallow were broken up in 1929 and the heavy rains at the end of December made it possible to cultivate stubble land in readiness for seeding. The majority of such land to be sown was worked over in January. In the absence of further rain seeding was commenced with ensilage mixtures and oats and barley for green feed towards the end of March. The sowing of oats for hay and grain followed in April, and pease and barley in May. All stubble ground, some 665 acres, was then sown, but germination was slow and very irregular. In the absence of rain, wheat seeding was practically held over until the end of June, awaiting the definite break, which occurred on the 27th of that month.

Although showers were frequent in July, seeding work was not seriously interrupted and wheat seeding was completed by the middle of the month. The total area sown was 1,165 acres, made up thus:—Experimental plots, 212 acres; wheat (farm areas), 205 acres; oats (for grain and hay), 425 acres; barley, 65 acres; pease, 80 acres; hay and ensilage mixtures, 83 acres; greenfeed, 95 acres. The late sown crops came away particularly free from weeds, while the early sown ones, oats especially, were quite otherwise. The rapid growth in July and the check in September have already been referred to. At this time, too, eelworms appeared to be doing a considerable amount of damage, especially in oat crops, though their presence was detected in almost every crop on the farm.

The field sown with ensilage mixtures in test plots was too backward at the normal cutting time, in early October, and the headlands of well-grown crops sown on fallow were cut for this purpose, together with 150 acres of the oats which had practically failed. Ensilage making was completed by the end of October, and the binding of oats for hay and for threshing purposes was well in hand. During November this work was completed and all oats for grain threshed. Barley was all taken off with harvesters in the latter part of the month, and pea harvesting, protracted by unfavorable weather, was also completed. In addition to damage by frequent showers and boisterous weather, grubs made their appearance again and accounted largely for the partial failure of this crop. At the end of November hay cutting was completed, but stacking was interrupted by other work. All wheat for threshing (that is, the produce of the permanent experiment fields, some 110 acres) had been bound and stooked and a start had been made with the harvesters and strippers in the larger fields. This work, together with wheat threshing and hay carting, was completed by the middle of December.

*Straw.*—In addition to the straw pressed during threshing, stubble was again cut with binders following the harvesters. In this way approximately 40 tons were saved and stacked in the fields requiring stock shelter. The quantity of baled straw stacked was 150 tons, and the cocky chaff and cavings heap at the thresher was estimated to contain 30 tons. The pressed straw was the produce of 308 acres, so that the average yield was just under 10 cwt. of clean straw per acre. The yield of grain was 11½ bush. in the case of wheat and 16½ bush. of oats per acre, or roughly 6 cwt. of grain per acre over the whole area cut for threshing.

## WHEAT HARVEST.

Seeding had been at the rate of 90 lbs. of seed with 1½ cwt. of high grade superphosphate per acre. In the farm areas the seed was dry pickled with copper carbonate, and in the test plots with copper sulphate, 1 per cent. solution, followed by immersion in ½ per cent. limewater and drying in the sun. Little or no trouble was experienced with any of the smut diseases; most varieties, however, showed a shrivelling of the grain, owing to causes already indicated. This was most marked in Field 6D, which

has been used for some years as a night paddock, and in which the soil dried out unusually quickly, owing, no doubt, to excess of the droppings of livestock. This accounts largely for the relatively poor returns in this field.

The total returns from wheat this year are shown in the next table, and the comparison between mean yields of this and previous seasons is shown in the table following.

TABLE V.—*Summarising the 1930 Wheat Returns.*

| Mean for 27 years ..... | —         | —      | —                 | 17 1                    |

It will be seen that, excluding the experimental areas, a six bag average was taken off, and this, in the circumstances, represents a satisfactory return.

The next table shows the returns from different varieties sown on the farm areas. These are not strictly comparable, as the fields vary in soil quality, and were, of course, sown at different times; the figures are given, however, as being of some interest.

TABLE VII.—*Showing Yields of Varieties of Wheat Grown in the Farm Areas, 1930.*

| Variety.             | Area.  | Yield per Acre. |
|----------------------|--------|-----------------|
|                      | Acres. | Bush. lbs.      |
| Sword .....          | 16.8   | 26 45           |
| Nawab .....          | 5.3    | 23 40           |
| Felix .....          | 7.1    | 22 8            |
| Late Gluyas .....    | 22.9   | 21 35           |
| Florence .....       | 6.8    | 21 24           |
| Waratah .....        | 5.0    | 20 54           |
| Nabawa .....         | 5.3    | 20 27           |
| Sultan .....         | 14.2   | 19 40           |
| Daphne .....         | 15.1   | 18 35           |
| Ford .....           | 10.4   | 17 58           |
| Sirdar .....         | 0.3    | 17 54           |
| Canberra .....       | 11.3   | 17 51           |
| Gluford .....        | 20.7   | 17 49           |
| Gluyas .....         | 15.3   | 15 29           |
| Federation .....     | 3.6    | 14 29           |
| King's White .....   | 13.7   | 14 15           |
| President .....      | 10.2   | 14 15           |
| Dan .....            | 13.7   | 12 12           |
| Faun .....           | 3.0    | 11 24           |
| Caliph .....         | 5.0    | 7 29            |
| Free Gallipoli ..... | 7.8    | 7 23            |

The last four named varieties were sown in Field 6D, and, therefore, suffered from the disadvantageous conditions referred to above.

The prominence of Sword in the above list appears to be significant. This variety has been one of the heaviest yielders in test plots each year since 1925, and still apparently retains the lead when sown under field conditions on a relatively extensive area.

#### VARIETY TRIALS.

The practice of testing each of the varieties of wheat of interest or importance locally, in triplicate plots of approximately one-tenth of an acre each, has now been in vogue for three seasons. These plots are sown in one field under, as nearly as possible, comparable conditions. For purposes of comparison between varieties the

figures representing the mean yields in these plots are those now employed, and the details of yields of all varieties sown this year are given later on. In the next table are shown the test plot results for 1930 in respect of all wheats which have been grown on the College farm for six years or more, together with the recorded yields of these varieties from 1925 onward, and the mean yields over this period.

TABLE VIII.—*Showing Comparative Yields of Varieties of Wheat Grown more or less Extensively on the College Farm during the past Six Seasons or More.*

| Variety.            | 1925. |    | 1926. |    | 1927. |    | 1928. |    | 1929. |    | 1930. |    | Means. |    |

The prominence of the variety Sword in this list is again marked, and the difference between its mean yield and the next highest figure, namely, a difference of over 5½ bush., is sufficiently important to warrant the assumption that Sword has definitely superior yielding qualities, at least under Roseworthy conditions. The next 17 varieties (down to Faun) in this list are separated by a maximum difference of only 3 bush., which may be largely covered by experimental errors, and no definite conclusions should, therefore, be drawn from the results shown with regard to their relative yielding capacities. Of the remaining varieties (from Dan onwards) almost all have some undesirable qualities, such as relative lateness of maturity, which militate against their success under hard conditions.

The next table summarises the results of the triplicate variety tests of the past three seasons and shows, as well, the individual yields obtained in 1930, the varieties being arranged in order of grain yields of this year.

TABLE IX.—*Showing Grain and Hay Yields of all Varieties of Wheat Grown in Test Plots, 1930, together with Mean Yields, 1928-30.*

| Variety.                | Breeding.                                        | Grain Yields per Acre. |                 | Hay Yields per Acre. |                 |      |

\* Denotes variety bred at Roseworthy College.

It will be seen that the relatively early varieties, and those recognised as being hardy under drought conditions, occupy the first dozen positions or so in the above list. In this year's hay returns the leading varieties stand in this order:—Sirdar, Captain, King's White, Zealand Blue, Maharajah, Huguenot, Sepoy, Regent, &c.

Taking the mean figures for the three years, the best 18 varieties, having regard to grain yields, are:—Sword, Nawab, Gluyas, Waratah, Regent, Florence, Gluford, Dawn, Canberra, Gloss, King's White, Currawa, Forel, Sultan, Felix, Faun, Nabawa, and Baroota Wonder.

Comparing the mean hay returns similarly, the best varieties stand in this order:—Crostan, White Tuscan, Leak's Rust Proof, Ford, Sirdar, Gluyas, Huguenot, Currawa, King's White, Canaan, Sword, President, Sultan, Turwey, Dawn, German Wonder, Zealand Blue, Mac's White.

The figures representing the mean grain and hay yields of the principal "dual purpose" varieties have been extracted from the last two tables and are now set out together in the next table.

TABLE X.—*Showing Mean Grain and Hay Yields of the Better Dual Purpose Varieties of Wheat.*

| Variety.           | Period.       | Hay Yield per Acre. |    |     | Period.       | Grain Yield per Acre. |    |
|--------------------|---------------|---------------------|----|-----|---------------|-----------------------|----|
|                    |               | T.                  | C. | L.  |               | B.                    | L. |
| Crostan .....      | 1927-30 ..... | 1                   | 13 | 27  | 1925-30 ..... | 18                    | 41 |
| Sirdar .....       | 1927-30 ..... | 1                   | 13 | 106 | 1925-30 ..... | 17                    | 37 |
| Ford .....         | 1927-30 ..... | 1                   | 11 | 64  | 1925-30 ..... | 18                    | 48 |
| King's White ..... | 1927-30 ..... | 1                   | 13 | 32  | 1925-30 ..... | 17                    | 35 |
| Sultan .....       | 1927-30 ..... | 1                   | 11 | 11  | 1925-30 ..... | 17                    | 27 |
| President .....    | 1927-30 ..... | 1                   | 11 | 10  | 1925-30 ..... | 17                    | 18 |
| Regal .....        | 1927-30 ..... | 1                   | 12 | 6   | 1925-30 ..... | 14                    | 40 |

There appears to be little to choose between the majority of the above varieties from consideration of the mean yields. Crostan and Sirdar, however, from their behaviour in the farm crop as well as in test plots, appear to show special merit for general farm purposes. As a hay wheat the latter has the special attribute of a solid straw, derived from King's White, which figures prominently in the ancestry of each. Neither, however, has inherited the beard of King's White, and each is apparently a consistent and fairly heavy grain yielder.

(To be continued.)

## A USEFUL BRIDGE.

On a recent visit to Kangaroo Island Mr. C. H. Beaumont (Horticultural Instructor) noticed a very simple, yet attractive, suspension bridge, which was serving a useful purpose over a river on the property of an orchardist. The bridge was constructed by straining a roll of Cyclone pig netting (square woven) across the river, battens being inserted every 15in. through the netting to form a foothold. The hand rails were made of several strands of fencing wire, from which droppers, also of fencing wire, were tied to the bridge, and stays were arranged by similar ties under the bridge and made fast to the banks. The bridge could be made more rigid and stronger by using a light wire rope on each side of the netting with similar ropes as hand rails and to hold the hangers. It could be made perfectly safe for children by including light wire netting on the decking and for sides. With strainer posts firmly fixed on both sides of the river, such a structure would not be easily damaged at flood times.

## ORCHARD NOTES FOR SOUTHERN DISTRICTS, FEBRUARY, 1931.

[By CHAS. H. BEAUMONT, District Horticultural Instructor.]

The main work of the month will be the completion of harvesting soft fruits and drying surplus fruits. The packing of apricots and peaches leaves much to be desired; ripe and green are sometimes rolled into a bushel box together, so that it is not surprising that prices are low. Drying of apricots and peaches has been dealt with in a pamphlet, which can be obtained from the department on enclosing twopence (stamp) for postage.

There will be few apples for export this season, and extra care will be necessary if they are to bring good prices; though we are short of apples, plenty will be sent from other States and will compete with ours. Pack according to regulations, and there will be no fear of rejection on the wharf; if any further information is required write to or call at the office of the Department.

Codlin moth is causing damage to the pip fruits, and there will be a big loss, even in the best sprayed orchards; this should be a good year to test out the white oils, with and without arsenate of lead. Use good water.

Pears are being offered for export, and with reasonable care should carry well; precooling seems to be a necessity for pears.

All racks, trays, and sheds should be thoroughly cleaned in preparation for drying vine fruits; do not take any risk of contamination by fruit moth; cleanliness is a dominating factor.

Vines are still liable to attacks of mildews if in showery or dewy weather, so it is well to keep watch and use preventives when required.

While trees are in full fruit mark those specially suitable for working from.

Scale insects on citrus are spreading rapidly now, and should be checked either by fumigation or by the use of white oils. Use good rain water and spray only on cloudy days or in the evening.

Irrigate young trees and vines, using fresh water only; loosen soil before it dries.

Pear slug or cherry slug should not be neglected—a light spray of arsenate of lead will kill it; dusting is easiest for hawthorn hedges, &c.

Silver leaf is very noticeable this year in pears, plums, and other fruits; cut out affected limbs, and paint cut with thick white lead.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

    ## IMPORTATION OF RUSSIAN WHEAT INTO THE UNITED KINGDOM.

---

Early in December the Agent-General for South Australia reported that he had been able to obtain much information which could be accepted as thoroughly reliable on the subject of the importation of Russian wheat into the United Kingdom. He intimated that a great deal of press and other publicity upon the matter had been tinged with political bias, and much of it could not be accepted as a reliable statement of the true position. There was a considerable difference of opinion as to whether or not Russia had been dumping wheat on the United Kingdom markets. The question, of course, depended entirely upon the interpretation given to the word "dumping." Without doubt large quantities had been landed in the United Kingdom in 1930. To the end of September the amount of wheat imported was only 45 per cent. of the total importation, but the Agent-General understood that during October nearly as much wheat came into the country from Russia as during the whole of the earlier part of the year, and that the amount received during November was approximately the same as that which came in during October. Imports from Russia were likely to cease during the winter months. Although this was stated in sections of the press to be due to the exhaustion of home supplies he was advised that it was really due to the closing of Russian ports, and that export will, without question, be resumed with the coming of spring and the re-opening of ports. There could be no doubt that the present unsatisfactory wheat position was not wholly due to the shipping of large quantities by Russia. There would seem to be a consensus of opinion amongst the leading merchants that the present position was largely an economic one. The high price paid for wheat following the war encouraged increased production, and the position was that production largely exceeded demand. This unbalanced position naturally tended to lower values, but there were other factors. The action of the Canadian Wheat Pool and the United States Farm Board in withholding supplies from the market last year, with a consequent heavy carry-over, had further aggravated the position. The United States export to Russia of large quantities of agricultural implements and machinery was also a contributory factor, as it necessitated the establishment of large credits abroad and Russia had adopted the present means to enable her to pay for her purchases. It was generally known that consumption in Europe, Canada, and the United States was very stable, and any change in the market up or down does not materially affect consumption, but in countries where a large proportion of the population was more or less on the starvation line, *e.g.*, China and Japan, a change in the market might perhaps be reflected in the demand position in those countries. The general position was certainly disastrous, and, so long as the world supply position remains in its present state, no hopes of any improvement are entertained. Competent market opinion was that low values would continue to rule for a long time to come.

While it was stated that Russian competition was unfair, this could not be definitely proved as particulars of production costs were not available. Russia's pre-war position as an important supplier of wheat must also be considered. The war and the results of the revolution caused the cessation of her exports for some years, but it was only to be expected that she would, as soon as the need arose and the opportunity offered, endeavor to regain her former position in the supply world. Of the exports this season the greater quantity had been sold on forward terms to United Kingdom buyers, and only relatively small quantities had come forward unsold. The price of Russian wheat sold in the United Kingdom had been comparatively low, and there can be no doubt that the low selling value had materially affected the United Kingdom markets, and would continue to do so.

*Imports of Wheat into United Kingdom from the principal sources of supply, together with total imports from all sources in the calendar years 1912 and 1913 and 1920 to 1929:—*

It is of interest to note that imports from Russia to the end of September amounted to 3,471,990 cwts. Of the imports for October from "Other Countries" shown above, 3,294,000 cwts. were received from Russian sources. The figures for November were not available, but it was understood that imports from Russia for that month were, approximately, the same as those for October.

EGG-LAYING COMPETITION, 1930-31.

Conducted at the Parafield Poultry Station under the Supervision of the Department of Agriculture.

Total No. of Pens.—Section 1. White Leghorns—204 birds; Black Minorcas—3 birds.

Section 3. Black Orpingtons—30 birds. Section 4. Rhode Island Reds—6 birds.

Twelve Months Test. To start on April 1st, 1930.

Section 1.—White Leghorns, 1 to 204; Black Minorcas, 205 to 207.

ADVISORY BOARD OF AGRICULTURE.

The monthly meeting of the Advisory Board of Agriculture was held on Wednesday, January 28th, 1931. There were present:—Messrs. F. Coleman (Chairman), H. N. Wicks (Vice-Chairman), P. H. Jones, H. S. Taylor, P. J. Baily, S. Shepherd, A. J. Cooke, A. L. McEwin, R. H. Martin, Prof. A. J. Perkins (Director of Agriculture), Dr. A. E. V. Richardson (Director Waite Research Institute), Mr. W. R. Birks (Principal Roseworthy Agricultural College), and Mr. H. C. Pritchard (Secretary).

Agents' Commission on Superphosphate.—The Committee appointed at the November meeting waited on the manufacturers on November 28th. Mr. F. Coleman said that the superphosphate manufacturers held out very little hope of being able to supply superphosphate at a reduced price during this season. Concession would be made to farmers who returned bags for refilling. The Secretary was instructed to get in touch with the Superphosphate Association for a formal reply to the request of the Committee.

Export of Pig Meat.—Information concerning exports of pig meat to London from Victoria was received, and the Secretary intimated that the report had been submitted to the Narridy Branch, from which the original question was asked. The letter from the Victorian department, written on December 4th, read:—"The quantity shipped from Victoria this season totals 5,040 carcasses—50 in September, 705 in October, and 4,284 in November. From inquiries made, it appears that pork is not shipped on consignment. The usual method of doing this business is to get cabled quotations and effect sales on same prior to shipment. At the moment, the best price offering from London is 7½d. per lb. for carcasses weighing from 60lbs. to 110lbs., with an average of 80lbs. This range of light weights is for consumption as pork. The cost of killing, preparing, and shipping comes to 2d. per lb., so that the price in Melbourne would be equal to 5½d. per lb. for porkers. The best offer from London for bacon weights, weighing from 120lbs. to 160lbs. carcass weight, is 6½d. per lb. The cost in this case also comes to about 2d., leaving 4½d. per lb. as the value in Melbourne. In both cases, it is understood that the quality is to be of the best."

Reduction in Agent Charges for Handling Wheat.—The Secretary stated that the Lameroo Conference resolution dealing with this was brought under the notice of the Chamber of Commerce and the Wheat Pool and that the handling charges had been reduced by ½d. per bushel.

Accounts for Cream Supplies.—The Redhill Branch submitted a resolution "strongly objecting to the present system of not showing expenses in making up accounts on cream supplies." This was submitted to Mr. Barlow, who states that "Previous to the Dairy Act becoming law the method of payment was to pay for an estimated amount of commercial butter. This estimation was based on the weight of the cream and the percentage of butterfat it contained, and a chart was used to indicate the amount of butter to be paid for. Under this system, a gross price was quoted and all expenses were then taken off. With practically all factories these deductions were comparable and were arrived at and fixed by a committee representing the manufacturing interests. When it was made compulsory for the factories to pay for cream on the butterfat basis, the usual procedure which applies practically throughout the world was adopted. That is to say, the factories fix a net price which they are willing to pay for butterfat and no expenses are shown, the manufacturing expenses, &c., being allowed for when fixing the net price. Departmentally, we have no control over this price as it is expected to be kept as high as possible by competition, and I must say that up to the present the prices fixed have been at least comparable. The reason that no manufacturing expenses are shown when paying for butterfat is that the butterfat is not the manufactured article, and the difference between the butterfat and

commercial butter (usually in the ratio of about 100 to 120) is used to pay part at least of the expenses. Either system, if under supervision, can be expected to give approximately the same net results, but it is practically impossible to show or charge manufacturing expenses if the payment is made for butterfat. The system at present in vogue is accepted throughout the world with the exception of New South Wales and Queensland." It was decided to advise the Redhill Branch accordingly.

Life Membership.—Life membership of the Agricultural Bureau was conferred upon Messrs. A. F. Herbert (Nantawarra), J. R. Coles (Longwood), A. S. Burgess (Water-vale), and J. Burton (Beetaloo Valley).

New Members.—The following names were added to the rolls of existing Branches:—Port Elliot—L. O. Hill; Waddikee Rocks—R. Scott, E. Rossiter, G. A. Graph; Mundalla—C. Hyde; Wallala—A. K. Weepers, A. Miller, J. McIntyre; Mount Pleasant—W. H. Johns; Kapinnie—A. Harvey, D. C. Wannan; Koonunga—V. Kindler, U. Gallasch, F. H. Schulz, A. Zwar; Wirrilla—P. O. Jacka, H. Jacka; Monarto South—P. O. Schenscher; Wolseley—I. Makin; Pinnaroo Women's—Mrs. F. G. Bonnin; Yeelanna—S. C. Shaw, H. O. Clements, J. W. Payne; Lamerloo—R. A. Jenkins; Parilla Women's—Mrs. L. Foale; Kangarilla—Roy H. Strickland; Langhorne's Creek—E. Dodd, I. Dodd; Tintinara—T. Ingliss; Scott's Bottom—H. Lohmueller; Strathalbyn—E. H. Woolfit, Dr. C. E. Willing; Two Wells—R. T. Murrell; Upper Wakefield—Alex. Anderson. Total number of members, 8,400; number of new members, 34; total number of branches, 305.

Conferences.—The Secretary intimated that Conferences of the Agricultural Bureau would be held at Lyndoch (Lower North) on Thursday, February 26th, and at Wirrabara (Mid-North) on Wednesday, March 11th. The Chairman promised to attend at Lyndoch.

HAVE YOU SEEN THE NEW MODEL 1930

ALFA LAVAL

There are 10 New Improvements, including
Ball Bearing.

Rust Proof Bowl, Rust Proof Discs,
Trailing Skim Milk Discharge from Bowl.

Year by year the ALFA LAVAL has led the way—each New Model has been by far the Best Separator in its day, but the 1930 New Model is far ahead of anything ever made before.

DAIRY AND FARM PRODUCE MARKETS.

A. W. SANDFORD & Co., LIMITED, reported:—

BUTTER.—The production at the beginning of last month declined and it became necessary to import moderate quantities of top grade butters from the eastern States; but since then quantities have steadied, and with the purchasing power of the public generally being restricted, there has been almost sufficient local butter for requirements. In lower grades, however, there is a surplus, and this is going forward to London from week to week. From this out, however, quantities will decline as usual at this time of the year. Owing to the acute rises in the exchange position, markets for butter in the eastern States firmed each week, and this was reflected from time to time in values here. At date the following quotations ruled:—Choiceest creamery fresh butter, in bulk, 1s. 6½d.; prints and delivery extra; second and third grades, 1s. 4½d. (These prices are subject to the stabilization levies.) Best separators, 1s. 2½d. to 1s. 3½d.; well-conditioned store and collectors', 11d. to 1s.; heated and pastry, 10d.

EGGS.—These also have shown a seasonable decline, and many of the consignments were variable in quality and careful attention was necessary in the testing and grading before sales could be effected. As the demand at present is more particularly for prime quality guaranteed eggs, there was a weakening demand for other sorts, but there was no alteration in values recorded. Ordinary country eggs, hen 5½d. per dozen, duck 6½d. per dozen; selected tested and infertile higher.

CHEESE.—The South-Eastern factories maintained quantities throughout the month under review. Local and Western Australian demand continued steady, so that clearances were effected each week. Rates firmed a point in sympathy with the hardening in butter values, and at date are as follows:—New makes, large to loaf, 7d. to 7½d. per lb.; semi-matured and matured, to 11d. per lb.

ALMONDS.—The new season's crop is now being marketed in limited quantities and the quality so far seems to be good. Demand continues sufficient to absorb lots as they came forward, and with little alteration in rates. Kernels, however, came in for better call, and are selling freely. Brandis, 7½d. to 7½d.; mixed softshells, 7d.; hardshells, 4d. to 4½d.; kernels, 1s. 6½d. to 1s. 7d. per lb.

HONEY.—This commodity is not moving out at all freely, and with heavy stocks held in all warehouses, buyers have been less eager to purchase than usual. The demand for lower grade is almost negligible even at low prices. Prime clear extracted, in liquid condition, 3½d. to 3½d.; best quality candied lots, 2½d. to 3½d.; second grade, 1½d. to 2d. per lb.

BEESWAX.—Moderate supplies, fair demand; 1s. 4d. to 1s. 4½d. per lb., according to sample.

BACON.—Curers have been able to obtain ample supplies of live hogs from the various markets, and consequently the quantities of bacon offering have been ample for all needs. Considering the times, the turnover has been well maintained, but an increasing call for bacon factory smallgoods resulted, which is usual during the summer months. Hams are in fair request. Best local sides, 9½d. to 10d.; best local factory cured middles, 8d. to 9d.; large, 7½d.; local rolls, 9½d. to 10d.; Geo. Farmer's "Sugar Cane" brand hams, 1s. 2d.; local hams, 1s. to 1s. 1d.; cooked, 1s. 3d.; "Sugar Cane" brand lard in packets 11d., in bulk 10d. per lb.; local prints, 10½d. per lb.

LIVE POULTRY.—The quantities marketed so far this year have not been so great as usual, and evidently the farmers have been keeping the hens so as to augment incomes from the eggs produced. Light-conditioned birds eased in values, but prime quality cockerels continued in good request. Values for ducks ruled lower than just previously and turkeys also are lower in values than was the case at Christmas time. Prime roosters, 4s. 9d. to 6s. 4d.; nice-conditioned cockerels, 3s. 6d. to 4s. 6d.; fair-conditioned cockerels, 2s. 8d. to 3s. 4d.; chickens lower. Heavy-weight hens, 3s. 3d. to 4s. 3d.; medium hens, 2s. 4d. to 3s. 1d.; light hens, 1s. 8d. to 2s. 3d.; couple of pens of weedy sorts lower. Geese, 3s. 8d. to 4s. 9d.; prime young Muscovy drakes, 3s. 6d. to 4s. 10d. Ducks, good-conditioned, 2s. 8d. to 3s. 4d.; do., fair condition, 1s. 9d. to 2s. 5d.; ducklings lower. Turkeys, good to prime condition, 11d. to 1s. 3d. per lb. live weight; do., fair condition, 8d. to 10d. per lb. live weight; do., fattening sorts, lower. Pigeons, 4½d. to 5½d. each.

POTATOES.—New local potatoes, 5s. 6d. to 6s. per cwt.

ONIONS.—New white or brown, 6s. 8d. per cwt.

"..... fire has a disinfecting, sweetening, and mellowing effect on 'new' land, which cannot economically be given in any other way"—said Mr. Spafford, Deputy Director of Agriculture.

In burning stubble the use of a Horwood-Bagshaw Fire Rake is infinitely to be preferred to the ordinary "running burn." Where the stubble is thin the rake will keep the burn going, and is not inclined to be as patchy as a running burn. Again, with a Fire Rake, it is not as necessary to be so careful in the choice of a day for burning. In new country the intensified heat from a Fire Rake will scorch roots, suckers, and shoots, which a running burn is inclined to miss. Further, the Fire Rake, in passing over the ground, misses nothing, collects and burns all the sticks and rubbish, and, in addition, gives the ground a light cultivation stroke.

The Horwood-Bagshaw Stump-Jump Fire Rake is made in light and heavy types, with two or three wheels; four sizes, 12ft., 15ft., 24ft., and 30ft. Write for our illustrated folder, giving full particulars of this implement, also copies of letters from enthusiastic owners. Write now whilst it's in your mind.

R In recess.

AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

REPORTS OF BUREAU MEETINGS.

WOMEN'S BRANCHES.

AUBURN WOMEN'S (Average annual rainfall, 24.08in.).

The meeting of January 30th was held at the residence of Miss Dennison. Sister Thomas gave an interesting paper, "Home Nursing," and Mrs. Giles read an article, "Diets in the Home." Twelve members and two visitors attended. (Secretary, Miss Dennison.)

BELALIE WOMEN'S (Average annual rainfall, 17.84in.).

Meeting held September 9th. Mrs. Mitchell presided over an attendance of 21 members and three visitors. Conveners were appointed for different sections to assist with the Bureau exhibit for the local show. Mrs. M. Baily gave an instructive paper, "Home Nursing." (Secretary, Mrs. E. L. Orchard, Jamestown.)

October 14th.—Present: 23 members and 30 visitors.

Mrs. I. Warnes, of Burra, gave an instructive address, "The Work of the Country Women's Association."

At the meeting held on November 11th, reports were received from delegates who represented the Branch at the Annual Congress. (Secretary, Mrs. E. Orchard, Jamestown.)

GLADSTONE WOMEN'S (Average annual rainfall, 16.40in.).

January 9th.—Present: 14 members.

DRESSMAKING.—Miss M. Brown read the following paper:—"Nowadays most women do a fair amount of their own dressmaking; even if it does not run to their particular frocks, they have a 'shot' at their morning frocks, especially those for summer wear. Even if we are proud of making our own clothing, we do not want everybody to know it is home-made, and, worse still, looks home-made. First of all, obtain a good pattern. *Cutting out* is the most important and cannot be done in five minutes. If the material is not cut out correctly the finished article cannot be expected to be satisfactory. Have a clear table, scissors and pins; use the best pins, to avoid marks in silk fabrics. Pin all patterns on the material first (because it would not be very pleasing if one proceeded with the cutting out first and then discovered not sufficient material). If it is a plain material, one can save a great deal, by placing the shoulder seams together, but in case of some printed materials and velvet, all patterns must run the same way. It is best to have the frock fitted and then pressed with the stitching, following the directions with the pattern. Finishing off counts for a great deal. Press the seams as the frock is being made. This point is very often overlooked. Then, perhaps, the dress is tried on before the finishing touches are added and it is not satisfactory. The sleeves, if there are any, do not set rightly; the collar sticks out; perhaps, if it is a coat, it hangs out at the bottom. The sleeves are usually most difficult to fit. Do not have the armhole too large or too small, and in case of a small armhole, do not try cutting out too much under the arm—let out the seam. To be on the safe side, tack the sleeve in and try on; sometimes the sleeve seem needs to come more towards the front. A few gathers in the sleeve helps a great deal, especially in cases where the wearer's arms are not so slim as they would like them to be, the sleeves pull across here and so split with arm movement, whereas a fullness allows for arm movement—and very few gathers are needed. In case of a collar standing out from the neck at the back, if cut too low it may be remedied by taking more on the shoulder, but first note that it will not interfere with the back in another place. Stretch the collar slightly on the neck at the back. A roll collar will never set satisfactorily if the collar is not stretched slightly on to the neck at the back. Should the back of a costume, coat, or sports

blazer hang out, take a little more on the shoulder seams near the sleeve—not at the neck. In the case of the front of the coat hanging apart at the bottom—this applies to a full length coat—take off at the shoulder seams again, only at the neck this time. *Pressing.*—Weight and time are more to be considered than heat in obtaining the best results. An iron used too cool will shrink the material. Try pressing on a small piece of the material first before the made-up garment, in case marks are left. If this happens, a cloth can be placed between the iron and the material. Velvet must never be pressed on the flat, but seams held at each end and passed over the iron to prevent marking. Another point, when handling velvet, take a cutting of velvet and place between the thumb and finger, holding pile to pile. Fancy crepes are pressed the same way as velvet, but velveteen may be pressed flat. Georgette and woollen fabrics must not be pressed under a damp cloth, where a number of other materials may. In a thick frock of, say, flannel, where there is a flat seam, rub soap on the seam. Very often steaming will improve a last season's frock. To do away with unnecessary fullness, place a damp cloth on the part and place a hot iron on that cloth. A shiney serge skirt may be improved by rubbing with a fine glass paper, not too hard, but just sufficient to roughen the knap and then press. Pressing marks may be removed by steaming. Place the damp cloth on the material, then hold the iron on the cloth for a few seconds, causing steam to rise. Slap the part with the open hand, then brush. Velvet may be restored, by holding over a basin of hot water. *Hints.*—When machine oil comes in contact with material, try stitching a piece of cotton wool on the mark. For a blood stain, put on damp starch and brush off when dry." (Secretary, Miss M. Sargent.)

KALANGADOO WOMEN'S (Average annual rainfall, 32.34in.).

January 10th.—Present: 14 members.

THE USES OF OLD WOOL.—Mrs. G. Ellison read the following paper:—"In these days of depression and lower prices for wool, women on the farm give consideration to the utilization in the home of odd fleeces, such as pet's wool, which are not usually shorn with the others. For this purpose, crossbred wool of a long staple is preferable. First place the wool in a kerosene bucket or copper to scour, adding a little washing soda to the water, and when just warm enough to get your hands into the water, wash well. Sometimes it is necessary to give two or three waters to get the wool nice and clean. Then dry out of doors; spread out on clean bags. When perfectly dry, start the carding or teasing process. For this, drive long nails through a thick piece of wood, in three rows of three, and nail the wood to a table. Then place the wool in lumps on these nails and then, with a comb made of many nails, knocked into another piece of wood, tear at the wool. The process is very simple and does not take long. I recently made a cushion out of wool, and it was quite a success, only that when scouring the wool I put in too much soda, and made it a little yellow." An excellent report of the Annual Congress was tendered by the Secretary, Miss A. Kennedy.

KANGARILLA WOMEN'S.

Seven members attended the meeting held on December 18th, which was devoted to a discussion on matters of local interest. (Secretary, Mrs. Steer.)

LUCERNE AND CLOVERS ALWAYS AVAILABLE.

EXPERT ADVICE ON GRASSES AND CLOVERS.

PARILLA WOMEN'S (Average annual rainfall, 14.95in.).

December 17th.—Present: 11 members.

GARDENING.—Mrs. Seidel read the following paper:—"There is no occupation more in accord with all that is best and brightest in the human character than the care of a garden. A lawn is refreshing to the eyes, and after it is covered, needs very little attention. I never water mine more than once or twice a month. As soon as it is long it must be cut to keep it smooth and green; the frost cuts it back a good deal, which makes it appear dead, but a layer of sand makes it shoot out fresh. In the mallee I find it hard work to grow a summer flower garden, but a lawn, roses, petunias, scabious, linaria, carpet of snow, and nasturtiums are easily grown with very little attention. Stocks do well in winter. Every two or three years they can be cut back and will flower profusely. Asters require a lot of water. Perennial asters and daisies are quite all right; the latter can be grown quite successfully here. Cosmos, sunflowers, and carnations also do well and do not need much attention. I never transplant when it is hot; wait for a cool change and cover the seedlings with straw or manure to keep them moist. Zinnias and dahlias do well, but require a lot of water.

USEFUL HINTS FOR THE HOUSEKEEPER.—At the meeting held on January 21st, which was attended by 17 members, the following hints were given:—Drooping flowers may be revived by plunging the stems into boiling water. A little turpentine mixed in black-lead gives the stove a better polish. Place a piece of greased brown paper over pound cake while baking to prevent burning. A little borax in blue water makes clothes a good color. To remove salt from soup, if soup has been salted too freely, boil some slices of raw potato in it for a few minutes, and the salty flavor will disappear. Add a teaspoonful of brown sugar if soup is too salt. To take the shine out of navy blue suits, rub well with strong blue water and press. A profitable way to use candle ends is to mix them with other materials to make floor polish, or placed between two rags and rubbed with a hot iron makes ironing much easier. A few drops of kerosene added to water for washing floors makes a nice glow on the floor. Discarded silk stockings rolled into a ball make a good polisher for mirrors, &c. To get rid of the smell of paint in a newly-painted room, place a handful of hay in a pail of water, and allow it to stand in the room. Ink stains on linen may be removed by dropping tallow from a lighted candle on the stain; let it remain on for a few days, then wash. If the stains are old and patchy, oil of lemon will never fail. A cheap way of preserving eggs. Prepare a solution of quicklime, 3lbs. lime, 1oz. cream of tartar, ½lb. salt, to 6 quarts of water. Allow it to become quite cold and then place in a petrol tin, covering the eggs. Lemon syrup—a cheap and easy recipe: 3lbs. sugar, 1oz. citric acid; on these pour 2 quarts boiling water, and when cold, add one small bottle of essence of lemon. Use a small quantity to a tumbler of water. Mix together 4lbs. clean sand, 4lbs. whiting, and one packet soap extract. This will be found a cheap and good cleaning powder for saucepans, tables, &c. (Secretary, Mrs. Welden.)

PARRAKIE WOMEN'S (Average annual rainfall, 14.52in.).

Fourteen members attended the meeting held on December 16th. The meeting took the form of a Question Box. (Secretary, Mrs. Cabot.)

PINNAROO WOMEN'S (Average annual rainfall, 14.70in.).

September 5th.—Present: 19 members.

The meeting took the form of a Question Box. The following questions were asked and answered:—How to treat diarrhoea in young chickens? *Answer*—Give Epsom salts on bread. Does it harm a cow to milk her until she comes in again? *Answer*—Yes; she will be much better for a few weeks' spell. What is used to make a pound cake very dark? *Answer*—Use the ordinary ingredients, but the longer the cake is baked the darker it becomes. A remedy to stop small green grubs eating off the tops of carrots? *Answer*—Use arsenate of lead as a spray on the plants. What is the best cure for fowls which develop colds in winter? *Answer*—Keep them out of draughty places. What is the best preparation for painting hen roosts?—*Answer*—Waste tractor oil, or, if not procurable, one part of kerosene to three of oil. What will remove phenyl stains from silk? *Answer*—Try new milk. How long should soap be kept to make it a good color. *Answer*—It should be a good color as soon as made, but left to stand four weeks before using. Why is it that the pieces in marmalade go hard and tough after it is a few months old? *Answer*—The pieces were not boiled sufficiently before the sugar was added. Why is it that a sponge on stewed fruit rises better than when the sponge is baked alone? *Answer*—The heat of the fruit helps the sponge to rise quicker.

A demonstration of cutting out a flared skirt was given by Mrs. Jordan at the meeting held on December 5th, which was attended by 13 members and visitors. (Secretary, Mrs. Atze.)

WARCOOWIE WOMEN'S (Average annual rainfall, 12.16in.).

The inaugural meeting of the Branch was held on November 11th. Eleven members were enrolled and officers elected. (Secretary, Mrs. A. Crossman.)

WASLEYS WOMEN'S, January 8th.

HOME DRESSMAKING.—Mrs. Wilson gave a designing and cutting-out demonstration and read the following paper:—"Have only a moderately hot iron for silks, or they will lose their sheen. Always press the seams open first, then if it is desired to bind them together, press afterwards. The successful hang of the frock largely depends on the pressing. The seams of delicate materials should be done with the point of the iron only. To shrink materials, wring a piece of calico out in a basin of water, place on material,

**Buy your Vegetables
with your Groceries
in
packets!**

WHEN next you make up your list of provisions to be bought, add to it Swallow & Ariell's Compressed Vegetables. They are easily prepared—economical—with the true vegetable flavour. Though only water is removed from them they have but a tenth the weight of fresh vegetables. Compressed Vegetables are easily carried, and as easily stored.

Carrots, Parsnips, Turnips, Onions, and mixed—in ½-lb. cartons and 1-lb. tins. Tomatoes and Rhubarb—in ½-lb. cartons. Beetroot—Loose, in 1-lb. tins. Mixed Vegetables—Loose, in 1½-oz. packets.

Ask your Storekeeper for:

Swallow & Ariell's
**COMPRESSED
VEGETABLES**

press until both the cloth and material are dry; go over all the material like this before cutting out. When doing muslin and voiles, press the whole of the material over afterwards on the wrong side when finished. *Machinery.*—See that the machine is well oiled and cleaned. Always thread with a finer cotton on the spool than on the top. Do not watch the needle when machining; watch the foot. To prevent the thread cobbling at the start, see that the cotton is at the back or on the right hand side of the foot. *Notes on Home Dressmaking: Purchasing.*—It is always more economical to choose a style before purchasing material. By doing this, one can then purchase what material is required. People so often buy a dress length of from three to four yards, take it to a dressmaker, choose the style and find they need half a yard or so of another material for trimming. Before cutting out be sure of the pattern. Buy a good pattern, measure it carefully, and alter it to suit your figure. A good, perfectly plain pattern is the best. It can be altered to suit any style or design. 1. To lengthen a bodice and skirt, cut 2in. above waist line and across hip line, which is 7in. below waist line, and spread. 2. To shorten, tuck pattern between waist and bust line and hip line. 3. To widen at hips and hem, cut pattern 2in. in from armhole to hem and spread. 4. Bust, cut from centre shoulder line to below bust line and spread. Bands and folds are cut on the cross. Frills set better if cut on the cross and half as much again is allowed for gathers. Box pleating is cut on the straight and three times as much allowed as the space to be covered. Kilting is cut on the straight and takes three times as much as the space to be covered. Facings for flared or shaped skirts should be cut to the shape of skirt if a wide facing is required. Usually they are French hemmed, the crosspiece stitched on the right side, turned over, and stitched on the first stitching on the wrong side, leaving a narrow band. Always see that the armhole fits correctly, then try the sleeve in the armhole. If it is the least bit too big to fit the armhole correctly, take it in at the seams. Do not, on any account, have the armhole larger than the sleeve, or the bodice will be out of shape. When putting in the sleeve, start about 3in. towards the front from under the arm seam of bodice, pin around under arm, and holding the bodice so that you are pinning inside, not on the outside, coax the sleeve gently in to place. Often a sleeve which appears quite out of proportion will fit in quite correctly if done in this way. When the sleeve is stitched in, press the seam well open, then take it together again to bind. Most people look to see if their frocks are well finished off inside when they come back from the dressmaker, but the French artists put as little stitching as possible into their frocks, the raw seams are hidden by a loosely fixed lining; and in summer frocks where no lining is used, I have seen the sleeve seams made tidy by hand stitching a piece of Valenciennes lace on to the outside piece of the seam."

Meeting held February 5th. Present: Mrs. E. Day (chair), 35 members, and four visitors. Mrs. P. Maloney, of Roseworthy, gave an address, "Literature." (Secretary, Mrs. M. Wilson.)

WILKAWATT WOMEN'S (Average annual rainfall, 16in. to 17in.).

November 18th.—Present: 11 members and five visitors.

Miss A. Sorrell read a paper, "Cake Making," which was discussed by members. Miss Sorrell also said if red ochre was mixed with linseed oil instead of water, it would have a surface which could be wiped over with a cloth. If roses affected with mildew were sprinkled with the hose and then dusted with sulphur, it would help to check the mildew.

THE KITCHEN GARDEN.—Mrs. A. Young read the following paper at the meeting held on December 16th, there being present 12 members and four visitors:—"One of the worries of the farmer's wife when it comes to preparing the dinner is the difficulty of getting fresh vegetables. Potatoes and onions keep for months if spread out in a cool, dry place. Root vegetables, if bought in quantities, may be kept fresh by burying them and keeping the soil damp. The easiest way of solving the problem is by having a supply growing in the back garden. Beginning with the summer, the nicest green is the bean (the dwarf variety for preference). I find the sparrow is a great nuisance to the tender, young bean plants. In January sow the first early cabbage and cauliflower seeds (a small variety of cabbage that hearts quickly as soon as cool weather commences). Then in April a larger kind can be planted, forming huge hearts, in the middle of winter. Then again in July the late class (such as Drumhead) is a good cabbage, and if kept damp, shows no sign of running to seed. If peas are sown to come ready in the early spring they bear longer and the plants do not dry off so quickly. At the end of winter broad beans may be sown, and if the bean is picked when about half to three-quarter grown, the whole of the bean may be sliced and cooked, and is much preferred by many to the cooked bean seeds. When a salad is wanted for a cold meat tea, what is nicer than lettuce or tomato salad? Lettuces are easily grown in this district through the winter months, but they need plenty of water, and the ground

kept damp all the time, to prevent them from scorching or running to seed, once the hot weather commences. Tomato plants should be planted out early in a spot well sheltered from the wind, and to get early tomatoes a good early variety, such as Early Dwarf, should be planted, with other sorts for later fruiting as well. Beside green vegetables there are plenty of melons and marrows that reward the grower by pleasing supplies. If a good crop of marrows or trombones is secured, the fruit will keep for months if, when picking, a piece of the stem is left attached to it, and then stored in a dry shady place. The seed of root vegetables may be planted at any time in a well-prepared bed which has been watered a fortnight before, and any weeds which have germinated in that time well raked in. This often saves time in hand weeding later. The hard, stiff clay soils need sand mixed with them to make them ideal for the garden, and one should remember, even when the ground has been dug with the fork and nicely turned over, that after a heavy rain, and when the soil has set down hard around the young plants, the hoe is a very useful gardening tool." (Secretary, Mrs. M. Pritchard.)

WILLIAMSTOWN WOMEN'S (Average annual rainfall, 27.7in.).

October 1st.—Present: 10 members.

MY EXPERIENCES WITH A CHAFF COOKER.—Mrs. Wild read the following paper:—"In these days when economy is so urgent, with most housewives looking for every possible means of saving, I think that a chaff cooker is one which would appeal to all cooks who have to buy fuel, whether it be wood, gas, or kerosene. My chaff cooker is made from a small bootbox, lined with paper. I made a bag of cretonne to fit a billycan which holds the food. A billy is better than a saucepan, because there is no handle to bother about. I have fastened the bag to the cretonne lining which goes over the chaff, and pressed the bag with the billy in it into the chaff, making a tight fit. I then made a mat to go into the lid of the box, and saw that the lid fits tightly, making the box quite airtight. I used cocky chaff; it is cheaper, lighter, and I think better than wheaten chaff, because there are no seeds in it, that by the heat and steam that may escape from the billy may start to germinate. I was very dubious of success when I first used it, and so first tried potatoes, which I put into the billy, which fits the cooker, and boiled the potatoes for about eight minutes, and then put the billy with the lid on into the cooker and left it for one and a half hours. They cooked splendidly. The next was some stewed chops; they were put into the billy with chopped onions, pepper (no salt), and other seasoning, and about a teacupful of boiling water, cooked on the stove for about five minutes, just up to the boil, put into the cooker, and left for nearly three hours. This made a beautifully cooked hot tea. Since then I have cooked cabbage, cauliflower, bread and butter pudding, potatoes, and spinach. Putting the spinach into a tin without water and putting the tin into the water in the billy, with the potatoes to be cooked, boiling it for about eight minutes, and then into the cooker, with the result of having both cooked nicely. Rhubarb, prunes, and many other dishes have followed, all with success. Of course, one must use common sense and not expect anything to cook without there is enough heat and enough substance heated, either in shape of food or water, to keep its heat long enough to cook the food. A chaff heater can only conserve the heat; it does not generate it. The principle is the same as a

TELEPHONE C. 4855-4856.

thermos flask. Another great saving of fuel is effected in washing-up water. Boil the kettle, pour the water into the billy after you have dished up the meal, and put the billy into the cooker. Put out the fire, and have dinner without bothering about hot water for washing-up. This should appeal to those with wood stoves, as well as any other. If one has a bathheater, especially a chip bathheater, hot water is easily obtained with very little fuel. My chaffbox is such a success that I am making one with three compartments, and have bought aluminium billies for it. One can be used for meat cooking, one for pudding, and one for vegetables; or, if any are not in use, I am making bags filled with chaff to put in so as not to have space for cold air to get into. Aluminium is the best vessel to use; it gets so hot and keeps its heat longer than any other metal, but a good stout tin or an enamel one can also be used. Salt should always be *added* to cooked food, not *cooked* with it."

Meeting held December 3rd.—Mrs. J. Spencer gave an instructive demonstration, "First Aid to the Apparently Drowned," there being present 11 members.

A special meeting was held on January 7th to consider arrangements for the Conference of Lower North Branches of the Agricultural Bureaux to be held at Lyndoch on February 26th. (Secretary, Mrs. Cundy.)

SOUTH-EAST DISTRICT.

MOUNT GAMBIER (Average annual rainfall, 30.82in.).

Mr. E. W. Tollner presided over an attendance of 14 members and 30 visitors at the meeting held on September 5th, when Mr. A. Sassanowsky gave an address, illustrated with lantern slides, depicting views taken on an extensive tour of America. (Secretary, Mr. G. Gurry.)

MUNDALLA (Average annual rainfall, 19.39in.).

Twelve members attended the meeting held on September 10th. Resolutions for the Annual Congress were discussed. An article, "Tractors, Trucks, and Travellers," was read by the Secretary, Mr. A. Ross, and an interesting discussion ensued.

TANTANOOLA.

The monthly meeting of the Branch was held on September 6th. Mr. R. Searle presided over an attendance of 14 members and visitors. The subject, "Flax Growing," was brought forward and discussed. Several members stated that they had obtained seed and intended conducting experiments. (Secretary, Mr. H. Kennedy.)

MIDDLE-NORTH DISTRICT.

(PETERBOROUGH TO FARRELL'S FLAT.)

BEEFALOO VALLEY (Average annual rainfall, 23.50in.).

Meeting held September 8th. Present: Mr. H. Cook (Chair), 13 members, and five visitors. Matters of local interest were discussed. (Secretary, Mr. J. Halsce.)

BELALIE NORTH (Average annual rainfall, 17.95in.).

Mr. A. H. Codrington, of the School of Mines, gave a demonstration of wool classing at Mr. F. Carmichael's wool shed, and in the evening delivered an address, "The Wool Industry." (Secretary, Mr. G. Carmichael, Jamestown.)

BLYTH (Average annual rainfall, 16.94in.).

Twenty members and four visitors attended the meeting held on July 25th, when an address, "Farming Fallacies," was delivered by Mr. W. C. Johnston (District Agricultural Instructor). It was decided that future meetings of the Branch should be held on the fourth Friday in each month. (Secretary, Mr. L. Muegge.)

REDHILL (Average annual rainfall, 17.02in.).

Mr. S. Crowther presided over an attendance of 12 members at the meeting held on September 2nd. Mr. H. Crouch read the Departmental Bulletin, "Improving the Farm Flock," which aroused a keen discussion. (Secretary, Mr. S. Pengilly.)

SNOWTOWN (Average annual rainfall, 15.78in.).

Meeting held September 13th. Present: 18 members. The meeting took the form of a Question Box. Several subjects of seasonal interest were introduced, and a good discussion followed. (Secretary, Mr. A. Hocking.)

LOWER-NORTH DISTRICT.**(ADELAIDE TO FARRELL'S FLAT.)****BRINKWORTH** (Average annual rainfall, 16.01in.).

Meeting held September 9th. Mr. E. Ottens presided over an attendance of 20 members. The Secretary (Mr. H. Ottens) read a paper, "How to Reduce the Costs of Wheat Production," and an interesting discussion followed.

LIGHT'S PASS.

September 8th.—Present: 42 members and visitors.

Mr. L. Plush reported on a trip of inspection to the River Murray irrigation settlements in company with Mr. J. B. Harris (District Instructor) and Messrs. F. W. and B. Boehm. Mr. Bert Boehm gave an address on pruning, with special references to competing in local competitions. He pointed out where pruners made mistakes in previous competitions, and mentioned how they could improve their work. His remarks were illustrated by practical work on apricot limbs and branches. On this occasion Messrs. Boehm Bros. (cup winners in the Pruning Competition) entertained the Branch to celebrate their success. (Secretary, Mr. C. Verran.)

LYNDOCH (Average annual rainfall, 23.71in.).

Mr. A. Springbett occupied the chair at the meeting held on September 2nd, which was attended by 15 members. The Agenda Paper of the Annual Congress and local matters were discussed. (Secretary, Mr. J. S. Hammatt, Williamstown.)

NANTAWARRA (Average annual rainfall, 15.90in.).

August 7th.—Present: Seven members.

THE SMALL WOOL CLIP AND ITS PREPARATION.—Mr. R. Uppill read the following paper:—"I advocate making as few lots as possible of fleece wool, having regard to the probable total bales. In a clip from one to two bales up to 10 or 15 bales only pick out the bad or odd fleeces, namely, broken, old, short, tender, kempy, doggy, and spotty fleeces, make them into a lot whether it be bags or a bale, and if not a bale up to 300lbs., put into bags. It is better to make the few outstanding bright fleeces of very best quality into not less than a bale, but be careful in that they are uniform in color, length of staple, character, and of good yield. The fleece should not be skirted too heavily, but take off the stained and sweaty edges first and any fatty ends, such as near the legs, on the forehead, showing stain or uneven length, but do not pull off with those any wool that belongs to the fleece. In a season like the present I advocate taking out the backs, these are not only carrying dirt, but are dry and parched on top, and, like stained pieces, spoil the stronger and cleaner part of the fleece. Bellies, if well put up always command good value; the stained edges and bad pieces should be taken off properly. Most shearers tear off a piece of well-grown wool from the lower ribs; this should be taken off and put with its own class, as it is not belly wool. The belly should be rolled up with the clean side showing and packed in layers. Pieces should be well picked and kept in their class, bad edges should go into their lot. If this rule is adopted throughout, there will be no need for any reclassing, as is sometimes done by the brokers on reaching the store. All small parcels are interlotted, so there is no

danger in the piece lots being small. Lambs' wool should receive some attention other than stained pieces, the short pieces one easily picked out and bagged, such as the wool from the legs, and any very young lambs that are only 'whitewashed' can go as one lot; here, again, will be found differences of several pence per lb., the moderate length staple can be kept looking fresh, and unless a good number of bales, only pick out the short wool and make one good lot of the other." (Secretary, Mr. N. Robinson.)

September 4th.—Present: Six members.

QUESTION BOX.—Questions were asked by Mr. A. Durdin, who was responsible for the evening. (1) Which makes the better fallow, cultivation or plough? Mr. K. Young preferred cultivating in dry years and plough in wet years. Mr. A. Herbert's experience of cultivated fallow was unsatisfactory. He ploughed shallow in preference to cultivating. (2) Which is the best cereal for hay? Most members favored oats, because it could be grown more cheaply than wheat and hay. Horses were brisker, although care must be taken of their shoulders. One member preferred wheaten hay to oaten hay for feeding long. He stated that there was very little demand for oaten hay outside own farm. (3) What is the best crop rotation for the district? Most members agreed to the three-year rotation—bare fallow, wheat, and grass or oats in preference to wheat for third year, if possible; or a two-year rotation—bare fallow, wheat. Oats were disposed of before the wheat was ready, and the oat stubble made made better feed for stock. Although oats and barley were low in price, costs of production were correspondingly low if they were produced on stubble ground. They had to be guided by the seasons. (4) Class of sheep best suited to a 600-acre farm? A flock of breeding Merino ewes crossed with Dorset ram where conditions were not too wet. In wet districts the coarse and long wool type was better. Closeness to market was another factor to be taken into consideration. (Secretary, Mr. N. Robinson.)

PENWORTHAM.

Meeting held September 4th. Present: 21 members. Mr. C. Goddard, of the School of Mines, gave an address, "The Sheep and Wool Industry." (Secretary, Mr. A. Jenner.)

YORKE PENINSULA DISTRICT.

(TO BUTE.)

ARTHURTON (Average annual rainfall, 16in. to 17in.).

Meeting held September 4th at the residence of Mr. T. Howlett. Mr. Neale, manager of the Maitland branch of the National Bank, gave an instructional address, "Finance." (Secretary, Mr. T. Howlett, Moonta.)

KILKERBAN.

Twenty members and two visitors attended the meeting held on September 2nd, when an address, "The Cultivation of Wheat," was delivered by Mr. W. J. Spafford (Deputy Director of Agriculture). (Secretary, Mr. A. S. Dutschke, Maitland.)

PETERSVILLE.

September 2nd.—Present: 10 members and two visitors.

HOW TO KEEP THE RISING GENERATION ON THE LAND.—Mr. A. Vandepeer contributed the following paper:—"This is a national problem, and one which must be solved if Australia is to make good. The drift toward the cities is primarily responsible for Australia's difficulties to-day, whether financial, political, or industrial. There are too many non-productive citizens for the economic working of a country which is essentially of a productive nature. Farm life must be made more attractive than it has been in the past, so that we can reverse the drift and persuade more people to settle on the land. Farmers should try and make farm life and farm work as attractive as possible to their children, so that there will not be the tendency to drift to the cities. Children should be given an early interest in the working of the farm, and should not be made to work too hard during the school age. Whatever the boys or girls have to do about the farmyard should be of interest to them. If they have to feed poultry, gather eggs, milk cows, or any other such jobs, they should be given a small part of the profit from it, so that the work will be of value to them and not a drudgery. When a boy starts he should not be worked too hard, and should be given reasonable time for recreation, so that he can play games, &c., or indulge in any sport or pastime which he desires. By

doing this he will not become discontented with his life, or desirous of trying something different. Education is of very great importance, and all children should be given a good schooling, and where possible every boy should be taught the rudiments of a trade which will be of use to him, and he can, if he so desires, practise in his spare time. Carpentering or mechanical engineering would be very suitable, and could be put to good use on a farm, as well as providing something different from the ordinary farm work, also making him more efficient than the ordinary unskilled workman in much of the work necessary on a farm." (Secretary, Mr. A. Dutschke, Ardrossan.)

WESTERN DISTRICT.

CARALUE.

Meeting held September 3rd. Present: 16 members. Delegates were appointed to attend the Wudinna Conference, and other matters of local interest were discussed. (Secretary, Mr. E. Marshall.)

LAURA BAY.

Meeting held September 2nd. Present: Mr. E. Barnett (Chair), 18 members, and four visitors. Matters in connection with the Conference of Eyre Peninsula Branches were introduced for discussion. Other subjects of local interest were also discussed. (Secretary, Mr. W. Edson, Ceduna.)

MUDLAMUCKLA.

August 2nd.—Present: 11 members and four visitors.

Mr. Watson gave a report of the wool-classing exhibition given by Mr. Goddard, of the School of Mines. Inquiring as to the best method of dealing with mallee shoots, Mr. Watson told Mr. McGuire that he considered the slasher more effective than the axe. Mr. Parsons said that using the harrows as a fire rake in the stubbles was a good method of ridding the land of shoots. (Secretary, Mr. T. Zippel.)

YADNARIE (Average annual rainfall, 14.09in.).

September 2nd.—Present: 14 members.

INTENSIVE RATHER THAN EXTENSIVE AGRICULTURE.—Mr. J. Deer read the following paper:—"When it is realised that it will soon be no longer possible to extend the boundaries where agriculture can be successfully and profitably conducted, it will be imperative for South Australian farmers to concentrate on intensive rather than extensive agriculture. In this direction scientific agricultural research will play an important part, but will be done by agriculturists themselves by the adoption of practical and commonsense methods. As the greater part of the State is suitable for wheat and wool, and as these products have the most stable overseas market, it is quite right that these products should receive first consideration. To adopt a system of alternate cropping would, in most cases, necessitate burning the straw, but this would encourage drift and have a tendency to impoverish the land, so that it appears necessary to adhere to a system of rotation cropping. As land sown with cereals has a much greater grazing value than natural grass or herbage, I suggest as a general rule a system of rotation. Bare fallow, wheat, and cereals in the drier districts seem to offer the greatest value. Where there is any tendency to drift

PARAFIELD POULTRY STATION.

C. F. ANDERSON, Manager.

oats should be sown in the straw. If the land is not sufficiently clean it could be worked with a disc implement. Under this system portion of the oats can be grazed and the balance cut for hay or harvested. Take as an example a farm comprising 900 acres. On a three-year system the grazing period, January 1st to December 31st, would be—(1) 300 acres bare fallow, followed by wheat, grazing period nil. (2) 150 acres oats for crop, grazed January 1st to March 31st 150 acres for three months. (3) 300 acres bare fallow, grazed January 1st to July 30th 300 acres for seven months. (4) 150 acres oats for feed, grazed August 1st to December 31st 150 acres for five months. Thus one would have approximately the following acreage for grazing:—January 1st to March 31st, three months, 450 acres. April 1st to July 31st, four months, 300 acres. August 1st to December 31st, five months, 150 acres. Under this system half of the land will be sown for crop, 300 acres for wheat, and 150 acres for oats, and the other half fallow and grazing. Normal years 150 acres of oats will yield about 100 tons of hay and 150 or 200 bags of grain, and the other 150 acres used for pasture will graze many more stock than land left out for grass or herbage. It prevents the land from becoming crusted, and it can be fallowed with a light plough. It also keeps the land comparatively free from grass, which harbors the take-all fungus. Oats, generally speaking, should be marketed in the form of produce. Sheep are very necessary on the farm, and although wool is a low price, sheep will always be a profitable side line. It may not pay to hand feed extensively, unless to carry over short periods, when portion of the surplus oats may be put to profitable use. Cows are good, and offer the most profitable use for surplus oats, but it is very important that cows kept should come up to the required standard. Milk, butter, eggs, meat, and vegetables go far towards keeping the home, and will become a more important factor as intense culture becomes more general. Good fallow sown with cereals most adapted to the district and well-bred, well-fed stock offer the maximum returns from a given area." (Secretary, Mr. C. Deer, Cleve.)

EASTERN DISTRICT.

(EAST OF MOUNT LOFTY RANGES.)

BUGLE.

September 9th.—Present: 10 members and three visitors.

HARVEST OPERATIONS.—The following paper was contributed by Mr. E. Smith:—
 "In order to assure smooth working and avoid vexatious delays during the busy harvesting period, it behoves the farmer to make a careful inspection of all machinery, &c., used in connection with same. The first machine in use will be the binder, and considering the rough usage it is subjected to, it is remarkable that troubles in this direction are not more numerous. It is put to work in rough and stumpy country, and as long as the fingers will, with a big heave of the tilting handle, clear the stumps, the platform suffers by having to carry the weight of the near side of the machine over the obstacle, which in a number of cases means a buckled platform, heavier running on account of the slats on the canvas bearing heavily on the dented platform, and the consequent wearing on the canvas itself. In most of our country one has to set the height of the platform to be sure of clearing the stumps, and this means that when cutting the machine is tilted more than it should be to assure perfect working, and the disadvantages are that the weight on the tilting handle is greater, and, further, that the hay will have a tendency to run up the canvas head first, resulting in bulky butts and uneven tying. In order to overcome this trouble I use, in a crop of average height, a hoop iron slat bolted to the near side framework of platform and laid across to the top of the canvas about 18in. from knife, the slat being long enough to bridge the space between the two canvases. This slat is a distinct advantage, in that it checks the speed with which the heads of the hay travel. In many instances, especially in the older type of machine, one is likely to experience trouble with the tying apparatus, the main factor being that the twine is not held securely while the knotter is completing its operation, and in most cases this is due to the fact that rubbish collects under the twine holder spring, or that the spring itself wants renewing. The annoying delay during hay carting of having to handle the untied sheaves can be overcome by a little more attention to the knotter, because after continued use the lip becomes too smooth to hold the twine when the knot is being made, and this can be overcome by tripping the machine until the knotter jaws are open and roughening the lip with a small file. In numerous instances one is compelled to cut a crop that contains short patches, and perhaps through lack of attention or otherwise the short hay is not in a compact sheaf sufficient to force

the trip, and consequently there is a compaction which prevents the operation of tying the sheaf; to avoid this the introduction of a wire from the bottom of the trip lever to the binder seat the operator, by pulling the same, can clear this obstruction. Care must be used, however, to see that this wire is placed so that it will not come in contact with the bottom ends of packer arms. *Strippers*.—Before taking these implements into the paddock I advise a thorough overhaul of all working parts, and especially see that the crown and pinion are meshing correctly. The renewals of these working parts are expensive, and can, to a great degree, be avoided if care is exercised. The pinion, when in gear, should be running level, and should there be undue wear on the outside of same, a thin leather washer should be inserted under the bearing nearest the pinion, and if the wear is on the inside of the pinion the washer should be placed under the bearing near the box of the stripper. There should be $\frac{1}{16}$ in. clearance between the tip of the teeth on the pinion and the bottom of the teeth on the crown wheel. In our district ordinary blacklead or graphite is ideal for use on the pinion, in that it does not hold the dirt to the degree that is apparent when using oil or grease. With the wider machines, having centre bearings, the set screws on the latter should not be forced tightly on to the bearing, but should have a fraction of clearance in order

METTER'S "NUOIL" DOUBLE GEARED SELF-OILING WINDMILLS.

IN SIZES FROM 6ft. TO 14ft. WHEEL.

The strongest, best lubricated, best designed, and best governed.

Pump more water on a lighter breeze.

No spring on automatic oiling system to break, and no sheet-metal oil conveyors to wear out.

Gained First Prize and Silver Medal Adelaide Show, 1922, 1923, 1924, 1925, 1926, and 1930 (no entry 1928-29).

Also Gold Medal at the All-Australian Exhibition, 1930.

A reliable and useful investment, and the popular choice of experienced pastoralists, farmers, and others.

METTER'S 5ft. "MINOR" WINDMILLS.

Most efficient for pumping water from shallow depths.

that the beater spindle can run true without pressure to force it into alignment. The ordinary oiling arrangements, especially on the beaters, can be improved upon by the introduction of bottle feeders. These feeders need attention only twice a week, and the saving of time and oil is apparent. Care, however, must be used to see that the end of the small wire feeder in the bottle rests on the spindle, for it is the action of the revolving spindle on this wire that provides proper lubrication. In respect to the woodwork on all farm machinery, after a stiff brushing to remove dirt, &c., a generous coating of heated raw linseed oil is the best means of preserving same, and on the stripper and waggon wheels the surest way of overcoming the necessity for frequent retyring. When reading reports in the *Journal of Agriculture* one repeatedly comes across recommendations to use boiled oil on woodwork. I disagree with this for the reason that boiled oil creates a film over the grain of the wood and prevents the oil from penetrating. I strongly advise farmers to endeavor to market as good a sample of wheat as is possible. We in Australia are at a great disadvantage so far as world's parity is concerned, in that we have been satisfied to produce an F.A.Q. sample and overlook the important factor that we are selling against countries which market graded wheat. An instance of lax

Stacking clover hay on property of Mr. S. Shepherd, Kyrbolite. Push-rake delivering hay to the mechanical fork.

Stacking clover hay on property of Mr. S. Shepherd, Kyrbolite.—Mechanical fork, operated by one horse, delivering hay to stack 21ft. high by an "other throw" movement. Estimated capacity, 20 tons a day; three to four hands. Note—The man on the fork is having a free ride to the stack—no need for a ladder.

methods was painfully brought home to us recently, when we were compelled to purchase seed wheat at 5s. and over per bushel from other districts, and growers would have been ashamed to have been responsible for the marketing of some of the samples supplied as true to type seed wheat. The question of guarantees and bonuses, &c., would not be necessary if the quality of wheat sold overseas was such that the necessity for a margin on account of rubbish, &c., made by the buyer was obviated, and the sooner the method of marketing is improved upon the sooner will our Australian wheat be in greater demand and better prices obtained." (Secretary, Mr. B. Auricht, Taldra.)

RAMCO.

Meeting held August 4th. Present: Seven members. A report on the year's work was read by the Secretary (Mr. J. J. Odgers), who stated that although the membership was small, attendance at meetings had been good. Each meeting had either a paper or discussion, and it was pointed out that interest of members in providing subjects was one of the factors of the Branch's success.

SOUTH AND HILLS DISTRICT.

BLACKHEATH.

Mr. H. Paech presided over an attendance of 10 members and visitors. Mr. A. Law read an article from the *Journal of Agriculture*, "Pig Raising where Lucerne can be Successfully Grown," and a keen discussion followed. (Secretary, Mr. E. Paech, Rockleigh.)

CHERRY GARDENS (Average annual rainfall, 35.03in.).

September 6th.—Present: 14 members.

The meeting took the form of a working bee, at the Soldiers' Memorial Park, in assisting in digging around the ornamental trees and shrubs. In the evening members met at the residence of Mr. H. Jacobs and reports of delegates to the Hills Conference were received and discussed. (Secretary, Mr. A. Stone.)

McLAREN FLAT.

Meeting held August 7th. Present: 25 members and seven visitors. Subject to the approval of the Dried Fruits Board members of the Branch decided to donate 1 ton of currants to organisations supplying meals to the needy in Adelaide. (Secretary, Mr. A. Bruce.)

September 11th.—Present: 21 members and three visitors.

AGRICULTURAL EDUCATION.—Mr. T. Williams read a paper on this subject. The speaker referred to the advantages to the producers of the various experimental farms, orchards, and farmers' plots, &c. Discussing the paper, members agreed that too much publicity could not be given to the valuable work that was being done at the Blackwood Experimental Orchard, and that an effort should be made to have the results of the various experiments printed. (Secretary, Mr. A. Brice.)

MOUNT COMPASS.

Meeting held September 4th. Present: 36 members and a number of visitors. Mr. A. Anderson gave an address, "Potato Growing." Mr. J. Black read articles dealing with the subjects, "The Australian Economic Outlook and "The Paterson Stabilisation Scheme." Mr. H. Peters drew attention to the prevalence of bloat in dairy cattle in the district, and advised members to provide for free access to dry fodder as a guard against the trouble. (Secretary, Mr. J. Black.)

MOUNT PLEASANT (Average annual rainfall, 27.38in.).

Meeting held September 12th. Present: Mr. Y. Tapscott (Chair) and seven members. Reports of the delegates who attended the Balhannah Conference were received and discussed. (Secretary, Mr. D. Stow-Smith.)

RAPID BAY.

Meeting held September 11th. Present: 14 members and two visitors. Mr. R. Hill (District Agricultural Instructor) delivered an address, "The Development of Pasture Lands." (Secretary, Mr. L. Morris, Delamere.)

SHOAL BAY.

Mr. H. T. Noske gave an interesting report of the proceedings of the Southern Conference held at Murray Bridge. (Secretary Mr. H. T. Bell, Wisanger, K.I.)

CROWN LANDS.

LIST OF LANDS OPEN.

The attention of intending applicants for land is directed to the Official List of Lands Open which is published half-yearly (in January and July). The list shows the areas, localities, prices, short general descriptions, &c., of the sections available, and the conditions under which they may be applied for.

Copies of the list may be obtained on application to the Director of Lands, Adelaide.

APPLICATIONS FOR LAND.

Intending applicants for any lands which are open for application are reminded that application may be made for the whole or any portion of a block. The Land Board has power to allot portions of a block if considered advisable, and to adjust the purchase-money or rent. If only portion of a block is applied for, deposit of a proportionate amount must be made, and the successful applicant would be required to pay cost of survey of the subdivision.

ADVANCES TO SETTLERS.

The administration of the various Acts dealing with advances to settlers has been committed to the State Bank of South Australia by the State Bank Act, 1925. All applications should be made to the Chairman, Board of Management, State Bank, Pirie Street, Adelaide.

R. S. RICHARDS, Commissioner of Crown Lands.

AGRICULTURAL PUBLICATIONS.

The following publications have been issued and are available for distribution at prices mentioned :—
 "First Aid to the Horse," by F. E. Place, B.V.Sc., M.R.C.V.S., &c. ; price, 3s. ; posted, 3s. 2d.
 Journal of the Department of Agriculture, 5s. per annum in advance ; 1s. per single copy to residents in South Australia. Other places, 10s. per annum ; single copies, 2s. each.
 The bulletins and leaflets may be obtained by sending a 1d. stamp for postage.
 All communications must be addressed—Ed., "Journal of Agriculture," Box 901E, G.P.O., Adelaide.

THE AGRICULTURAL BUREAU.—Particulars of this Organization, of which every farmer should be a member, can be had on application to the Department.

MORE AND BETTER GRASS.

Pasture improvement precedes pasture top-dressing, because the best pastures pay handsomely for the best treatment. You can INVEST more money in top-dressing and obtain a better DIVIDEND... and this quite irrespective of the kind of farming you carry on.

The addition of NITROGEN to Superphosphate is the latest development in grassland farming, and foremost farmers in all districts of good rainfall, or where irrigation is practised, are realising the advantages of

SULPHATE OF AMMONIA

Here is the opinion of a Victorian farmer who has just completed a trial:—

“Results have astonished me, for the two plots treated with Super and Sulphate of Ammonia have carried exactly double the stock that the plot treated with Super only has carried.”

AGRICULTURAL VIEWS AND COMMENTS.

Agricultural Bureau Conferences.

District Conferences of Branches of the Agricultural Bureau are being arranged as follows:—

South-East, at Kalangadoo (Secretary, Mr. J. Dignan), March 18th.

Yorke Peninsula, at Maitland (Secretary, Mr. T. H. Howlett, Arthurton), April 15.

The above Conferences will commence at 10.30 a.m. in each case. Papers and questions for Conferences should be sent to the General Secretary, Agricultural Bureau, about a fortnight prior to the respective dates mentioned.

Publications Received.

The Library of the Department of Agriculture acknowledges the receipt of—

“Agricultural Research in 1929.” (Price 1s. 6d.). Published by the Royal Agricultural Society of England.

AGRICULTURAL INQUIRIES.

[Replies supplied by Mr. W. J. SPAFFORD, Deputy Director of Agriculture.]

Solubility of Superphosphate.

I have noticed on working the soil after harvesting a cereal crop, and also when digging potatoes, small particles of superphosphate; have these particles of super lost their value, or is it still available for future plant life? (Blackheath Agricultural Bureau.) Reply—Superphosphate consists in the main of water-soluble phosphate of lime and gypsum in almost equal proportions, and the white particles found long after the superphosphate has been applied are largely composed of the gypsum. Most of the phosphate of lime, which is soluble in the soil moisture, is absorbed by the plants before they reach maturity.

Good Crops on Soil-eroded Paddocks.

Why did ground which had the top soil washed away produce a better crop on it than the ground one would consider good fallow with a good tith? (Narriady Agricultural Bureau.) Reply—In certain seasons it is not so very unusual to find that where light soil has drifted off the surface, even down to the depth of ploughing, or where the soil has been washed away, better crops are received than from normal fallow. In our experience of this happening it has always occurred in those seasons when the distribution of the rainfall has been such that the cultivated land has not been properly packed together. We have seen several cases of it during this past season, and in every single instance the ordinary fallow, where the crop was not so good as on the washed or drifted area, had remained loose and open. Wheat plants demand compact soil, and in dry years it is more important to pack the fallow together at seeding time than in wetter years, because in the latter case sufficient winter rain falls to correct excessive looseness of the soil.

Can Stable Manure Replace Superphosphate?

“If stable manure be dried, sieved, and run through the seed drill, would it replace super, and, if so, what quantity would be required?” (Eudunda Agricultural Bureau). Reply—Superphosphate is applied to crops to make up the shortage of phosphoric acid,

and for our conditions the only manures that can replace superphosphate are those containing an equal amount of this plant food and in a water-soluble form. One hundred-weight of superphosphate (45 per cent.) contains 23lbs. phosphoric acid, and ordinary stable manure only contains about 7lbs phosphoric acid to the ton, but when this latter material is properly air-dried, the content of phosphoric acid will probably be about 15lbs. per ton. If the comparison between superphosphate and stable manure ended there, it would be a simple matter to calculate how much to use to equal a given dressing of superphosphate, but the phosphoric acid in the stable manure is in an insoluble form, whereas in the superphosphate it is soluble in water.

Insoluble phosphates are not suitable for wheat crops in our conditions, and large quantities of added organic matter are not helpful for wheat, particularly where bare fallowing is practised, and so for these two reasons stable manure will not economically replace dressings of superphosphate in any district in South Australia.

Rye Grass for Natural Pastures..

“H. L.,” *Inman Valley*, asks “What is the best plan to adopt to establish rye grass for grazing on an unbroken pasture”? Reply—If it is desired to establish some green feed during the dry months, rye grass is hardly the plant for the purpose, because it is not green in February or March, except in damp locations or where irrigation is practised. A better grass for the purpose is *Phalaris tuberosa*, but the outstanding plant, where it can be grown, is lucerne, both of which require good soil preparation before seeding. Perennial rye grass will grow well in your conditions, but you would be very fortunate to get a good stand unless sown on cultivated land. Wimmera rye grass will do fairly well and can be established without much soil preparation, but it does not supply green feed in the summer. It is only an annual, but seeds itself with the same certainty as does barley grass. If your land is loose enough for the seed drill to make decent tracks in it, in March or early April you could drill in superphosphate and 8lbs. Wimmera rye grass and 2lbs. Poverty Bay or Hawke’s Bay rye grass seed to the acre before the first autumn rain, then thoroughly harrow the land. To make more certain of success it is essential that the seed be put in before the ordinary pasture plants germinate, so that they all get a start together, for if you seed the land after the germination of the feed, the seedlings of the introduced plants cannot compete with those already up.

Flocculating Soil Agents.

“Does lime act mechanically on a stiff soil in a similar manner to a quantity of sand, or is there a chemical action therefrom which loosens stiff soil?” (Scott’s Bottom Agricultural Bureau). Reply—Lime, gypsum, and a few other substances are known as “flocculating” agents when applied to soils, i.e., they lead to the creation of an artificial coarseness of texture by the flocculation of the soil particles. Their action is essentially a mechanical one, in that they cement some of the particles together. The stickiness and heaviness of clayey soils is due to the fact that they contain a relatively high proportion of extremely small, flaky particles. When some of these are stuck together, the stickiness is overcome.

If a clay soil is shaken up with water, the water will remain muddy for a very long time, even for years in some cases, after the heavier particles have settled to the bottom. This muddiness persists because some of the clay particles are so fine and flaky, and as a consequence possess little weight and a relatively large surface area, that they remain in suspension in the water. Now, if a little of one of the flocculating agents is added to the muddy water, the clay particles quickly settle to the bottom and the water becomes clear. This is brought about because some of the clay particles are cemented together to form larger particles with increased weight and reduced surface. In soils these substances bring about the same result.

HORTICULTURAL INQUIRIES.

[Replies supplied by Mr. GEO. QUINN, Chief Horticultural Instructor.]

Black Aphis in Cherry Trees.

Commenting on specimens of diseased foliage of a cherry tree forwarded to the Department of Agriculture for identification, Mr. Geo. Quinn (Chief Horticultural Instructor) says from the external appearance of the foliage he is of the opinion that their curled and stunted condition had been produced by an attack of the black aphis of cherry (*Myzus cerasi*), which occurred probably in November or December. When the curled up folds were opened out, they enclosed myriads of moulted skins of aphides, which strengthens the above view as to the causal organism. At any rate, the general appearance is identical with terminal leaves on cherry trees to be found here and there in the Blackwood collection, where a slight and late attack of this pest was experienced this season. The precautionary measures lie in watching for the aphides on the tips of the young shoots in early summer, and if detected before they have been there long enough to cause the leaves to curl, a good drenching with Black Leaf 40 nicotine in soapy water applied as a spray will stop them, but success depends on prompt action.

DAIRYING INQUIRIES.

[Reply supplied by Mr. H. B. BARLOW, Chief Dairy Instructor.]

Concentrates for Dairy Cows.

Following a recent statement concerning the feeding of concentrates to dairy cows, Mr. H. B. Barlow (Chief Dairy Instructor) has informed a correspondent at Tailem Bend that the most suitable concentrates to feed are naturally those most easily and cheaply procurable, such as bran and crushed oats, and the addition of a little linseed meal would be advantageous. Mixing bran and oats in equal weights and feeding at the rate of 1lb. of the mixture to each 4lbs.-5lbs. of milk is very sound. Probably a mixture consisting of 100lbs. bran, 100lbs. crushed oats, and 25lbs. linseed oil would be more ideal and could be expected to give improved returns. Concentrates are usually better if fed with a little chaff in a dry state at milking time. The dry feed will tend to counteract the laxative effect of lucerne and is preferable and cheaper than pollard.

For fattening calves, feed as much skim milk as the calf will drink, provided it is not allowed to drink so much at one time that it shows signs of being badly "blown." After the first month, gradually increase the amount of linseed provided there is no indication of scouring. The main thing is to make any increase for alteration very gradually. If calves are tied up for about half an hour after feeding, they will not be so liable to suck each other; also, if they are given a box with chaff, crushed oats, and a little linseed to pick at, the effect will be good and also tend to eliminate the sucking. Once they have acquired the sucking habit it is hard to cure, but putting a little "bitter aloes" on the ears will check them considerably.

POULTRY INQUIRIES.

[Replies supplied by Mr. C. F. ANDERSON, Government Poultry Expert.]

Roup.

H. G. Le G., Coomandook, reports chickens standing about, crops empty, but no attempt to eat, mouths open, and a white cheesy substance close to the top of the windpipe. Reply—The trouble with the poultry is roup, and when in the form as described in this

FORD ADAPTABILITY

Ford Stakebed Truck fitted with all-steel dual-wheel equipment, recommended for rough conditions and for haulage over sandy tracks. In Canada approximately 40% of trucks now sold are dual-wheel equipped.

Ford Truck with six-wheel equipment for heavy and bulky loads. This unit carries a 12 ft. x 6 ft. body. On difficult and uneven roads six-wheel equipment increases traction and eliminates strain.

Trailer attachments increase capacity and reduce haulage costs. Loads up to 4 tons are carried by Ford six-wheelers with four wheel trailers at only 15 to 20% increase in the cost of operating the standard 30 cwt. Truck.

The New Ford Light Panel Van affords complete protection for half-ton loads. It is stylish and speedy; generous in loading space and economical in upkeep.

From the half-ton load to heavy haulage . . . Ford trucks offer lowest cost per ton mile. » » »

THERE'S a Ford Truck for every haulage task, and always with remarkable economy in first cost, upkeep, and efficient service. More than twenty Ford standard body styles meet every requirement, from light deliveries at high speeds to two-ton haulage over long distances. For heavier, bulkier loads, Ford six-wheel equipment and dual rear wheels are available, offering unusual power and economy. Special vehicles for special needs can be supplied at prices far below trucks of similar power and capacity.

Calculate your haulage costs—then ask your Ford Dealer to show Ford figures for your work.

The Improved Ford Truck, with new torque-tube drive and rear radius rods, offers long life and fine performance under the most difficult conditions and driving abuse . . . It is, indeed, Value far above the Price.

PRICES: Ford Light Commercial Models from £223; $\frac{1}{2}$ -ton Chassis £190; 30 cwt. Standard Dropside Truck £255; 30 cwt. Chassis £220. All prices F.O.B. nearest Ford Works . . . Sales Tax Extra.

FORD MOTOR COMPANY OF AUSTRALIA PTY. LTD.

V.C.38/

case, it is very difficult to cure. The trouble is very infectious, and all affected birds should be isolated. The growth in the throat can be removed by sharpening a small piece of wood at one end and scraping the growth away, then apply powdered bluestone or iodine to the affected part. It seems evident that the trouble has started with a cold. Examine the nose of the birds for any discharge present. Make a weak solution of permanganate of potash and dip the head of the bird right in. Repeat daily.

Chick Disorders.

The Secretary of the Pinnaroo Women's Branch asks—*What is the cause and cure for a disease amongst chicks when they are about one month to six weeks old, the toes of the birds crumple up and the chicks are unable to straighten them out, they appear only to be able to shuffle along?* Reply—The trouble may be caused through the chickens perching too high from the ground, and, when jumping from the perch to the ground, both the feet and legs are injured, or it may be due to the chickens being confined in an area, the surface of which consists largely of limestone, &c., which is too rough for the delicate joints of the chickens to stand. Again, the trouble may have been present to a lesser extent from the time the chickens were hatched, on account of a lack of moisture in the incubator or under the hen; as these chickens were apparently hatched during December—a difficult hatching time, unless plenty of moisture is supplied.

Hens Eating their Eggs: Use of Rabbits for Food.

The Blackheath Branch of the Agricultural Bureau asks—*What is lacking in the food of poultry which causes the birds to eat their eggs, and how should rabbits be prepared for food for the birds?* Reply—The cause of egg eating may be due to the absence of greenfeed. I incline to the opinion, however, that there are probably one or two birds which first start the trouble. If a close watch is kept, and these can be detected and removed from the flock, the trouble ceases. Again, it may be due to insufficient nests, and the birds laying round the farm. Egg eating is not so prevalent where plenty of nests are available and sand or shell grit put in the nests. In feeding rabbits, the best method is to boil them.

Feeding Ducks.

The following questions were forwarded by the Marama Branch of the Agricultural Bureau:—(1) *Can hard wheat be fed safely to Muscovy ducklings two months old?* (2) *What feeding is recommended for these birds?* Replies—(1) Hard wheat is suitable for ducks and will not kill them. (2) More suitable feeding is a wet mash compound of one part bran, two parts pollard, 50 per cent. green feed, and 1lb. meat meal per 100 birds. If required, crushed wheat can be substituted for pollard, and boiled rabbits for the meat meal.

Roup in Turkeys.

The Wasleys Branch of the Agricultural Bureau asks "*What is a cure for turkeys with swollen heads.*" Reply—The trouble with the turkeys is roup. It is very infectious and difficult to treat. Isolate all affected birds. The swelling must be operated on by cutting across the swollen part and forcing out the contents of the swelling; paint the wound with iodine daily until healed. It may be found necessary to place the fingers inside the mouth of the bird so that all the matter can be forced out. This disease frequently starts in the nostrils, caused through the birds foraging, and when drinking various particles of dirt, &c., the nose becomes clogged and the bird is unable to breathe freely. It is always advisable to keep all dirt and foreign matter away from the nose. This can be done by periodically wiping the nose with a rag dipped in kerosine. A few drops of kerosine in the drinking water are also effective.

Diarrhoea.

"The Cause of and Cure for Diarrhoea in Poultry." (Lyndoch Conference). Reply—Diarrhoea can be attributed to several causes, among the most prominent of which are:—(1) Unsuitable food and water; (2) diarrhoea caused through poultry tick and round worms. Diarrhoea in the case of unsuitable food and water is generally of a whitish color and the birds are badly scoured. The cure in this case is the provision of proper food and water. The most prominent cases of diarrhoea, however, are caused either through poultry tick or round worms, the cause of which can usually be identified by the color of the droppings. In the case of the former, the color of the droppings is of a distinct green, the birds have a high temperature, and are usually very thirsty. The remedy in this instance is the eradication of the tick, especially in the perching area. The perches should be so constructed that they are kept away from the walls and back of the house, so that the tick are unable to reach the birds during the time they are on the perches. The perches should be easily removable so that they can be regularly treated with a 10 per cent. emulsion of kerosine and soapsuds, to which gear-box oil or any similar oil can be added; once a week is effective.

Diarrhoea due to round worms can be easily distinguished to that of poultry tick by the color of the droppings. Where round worms are responsible for the trouble, the droppings are of a distinct mustard color, the feathers appear ruffled, and the birds have usually a listless appearance. Onions fed at the rate of 7lbs. per 100 birds once a week are effective. Turpentine one part, olive oil four parts, at the rate of one tablespoonful of turpentine to each 20 birds and fed after the birds have been fasted for 12 hours, is also effective. Nema capsules, obtainable from any poultry requisites store, are also certain in action.

Table Poultry.

"The Best Way to Make the Raising of Table Poultry a Payable Proposition." (Lyndoch Conference). Reply—The selection of a suitable breed of fowl for the purpose. It must be kept in mind that the demand is for a bird that will dress at 4lbs. to 4½lbs. The Black Orpington, Buff Orpington, Rhode Island Red, Plymouth Rock, or Light Sussex will be found very suitable. The Black Orpington should claim preference; the hens lay a larger number of eggs than the other breeds and the cockerels are quicker growing. Black Orpington cockerels should be ready for marketing purposes at from 5 months to 5½ months, providing they have been properly fed. The time of hatching is also a deciding factor, for the reason that chickens hatched during certain periods do not make satisfactory growth. Hatching from early July to end of September is advised, and from early January to early March. The cockerels should be separated from the pullets as soon as the sexes can be determined. Birds for table purposes should be fed on two wet mashers a day, composed of two parts bran, two parts pollard, 30 per cent. green feed, mixed with skim milk. For the last three weeks, the birds should be confined in special fattening pens without runs. Where runs are attached, the birds are difficult to fatten owing to the exercise they get in the yards, and during these three weeks they should be given as much wet mash as they can eat. Where pollard is not available, crushed wheat can be substituted.

Feather Eating.

"A Cure for Feather-eating Fowls!" (Lyndoch Conference). Reply—Feather eating, if undetected at the start, is often difficult to cure. It is caused at times by a deficiency in feeding, but more often the trouble is a form of cannibalism. The trouble, if seen early, can be easily stopped. It is usually started by one or two birds, and if a close watch is kept on the birds, it will be noticed that a bird will peck a few feathers from one bird, will pass on, and peck a few more from another bird, and continue in this manner. The habit is quickly acquired by other birds, and in a short time becomes general throughout the flock. If the first few birds are noticed at the commencement of

the trouble and removed from the other birds, the trouble will usually be checked. If large numbers of birds are affected, the feeding of the birds four or five times a day attracts their attention from the feather-eating habit. The application of Stockholm tar to the pecked birds will often check the trouble, the offending birds not liking the taste of the tar will stop feather eating. Where only a few birds are kept, the paring of a little from the top beak, so that the bird cannot close the beak sufficient to hold the feather, will prevent the trouble. A frequent cause of feather picking is when birds are heavily infested with feather-eating lice, the lice causing irritation to the bird. Dusting the birds with insectibane will kill the lice.

VETERINARY INQUIRIES.

[Replies supplied by Veterinary Officers of the Stock and Brands Department.]

"H. A. F.," Gawler, has been using various preparations in an endeavor to get cows in calf. Inquirer has two cows which, although repeatedly served over a considerable period, do not get in calf. Reply—I do not think that the medicaments you refer to will be effective in producing the desired results. It is doubtful if you will succeed in getting the older cow in calf again since she has "missed" for so long, but the following treatment for both cows is the only one that you can attempt and that is likely to give you results. Next time the cows come "in season," make a note of the dates, but do not allow them to be served. After the heat period has passed off, commence douching each cow every second day with a solution of Condyl's crystals (one flat teaspoonful in 1 gall. lukewarm water). Continue this treatment for a fortnight, then subsequently, till the cows next come into "season" again, douche every second day with a solution of common salt, one teaspoonful to each pint of warm water (use about 1 gall. of solution per douche). When the cows come in season again, douche out once with a solution of baking soda (not washing soda) one or two teaspoonfuls to each pint of warm water half an hour before service.

"R. K. W.," Yeelanna, reports cow with the skin peeling off her udder and nose. Reply—The information supplied in your query is very little, but it appears as if the udder came in contact with some irritating substance. The fact that the nose was scalded could be accounted for by the cow licking the irritated udder. Treatment would consist in washing the udder with warm water and soap and later swabbing several times daily with a solution of bicarbonate of soda. Subsequently, anoint with zinc oxide ointment or vaseline.

"C. L. B.," Karoonda, reports horse, eight years old, good worker, gradually lost condition until now is very thin and weak. Reply—Starve the horse for 18 hours (allow water) and at the end of that period give the following drench:—Raw linseed oil 1½ pints, turpentine, four tablespoonfuls. Subsequently give a teaspoonful of powdered nux vomica night and morning for 10 days; to give, mix with treacle and smear well back on the tongue. Feed horse on good quality chaff (damped) and add a good ration of bran and also some crushed oats (if available). When feeding horse, it is advisable to divide the daily feed into five small feeds, as better results are then obtained.

"R. E. H.," Koonunga, has horse, 13 years old, walks on her toe, and when standing rests with the hoof turned back so that the crown of the hoof touches the ground, and the animal has been like this for nine months. Reply—The condition cannot satisfactorily be diagnosed without an examination, but it appears to be either (1) a paralysis of one of the nerves (popliteal), (2) a contracted back tendon. As the condition is an

old-standing one I cannot suggest any treatment which would be successful. However, horses which are "knuckled," if worked slowly and on soft ground, may be made useful for a long time by applying a long-toed shoe, though this will not cure or even improve the original disease. It would be advisable to get a blacksmith to make the shoe.

"W. A. M.," Meribah, reports two pigs, 18 months old, off food, sow has lost use of back legs. Reply—The trouble was apparently in the first place constipation, and a purgative dose of 3ozs. to 4ozs. of Epsom salts in slop feed would soon correct that. The continued weakness trouble in the sow will be due to the strain of pregnancy and indicates some mineral deficiency in the diet. The animals, especially the sow, should each be given ½oz. sweet ground bone meal in the feed daily. In addition, the sow could with advantage be given one teaspoonful of cod liver oil night and morning. Chopped green feed given in limited quantities daily would, if available, also be very helpful.

"T. H. E.," Allandale East, asks do calves become infested with stomach worms and can they be drenched safely with bluestone? Reply—Cattle do become infested with stomach worms (*Haemonchus contortus*), but do not suffer so severely from these parasites as do sheep. The bluestone solution as prepared for treating sheep, may be used in doses ranging from 3½ fluid ozs. for calves to 10½ fluid ozs. for adult cattle.

"A. P. B.," Goondooloo, reports three horses rapidly losing condition, and one of the animals has a severe cough. Reply—The following treatment is suggested:—(1) Starve for 18 hours (allow water only). (2) At the end of that time give the following drench:—Raw linseed oil, 1½ pints; turpentine, four tablespoonfuls. When giving the drench, shake up thoroughly and give slowly by the mouth. (3) Subsequently give a tablespoonful of Fowler's solution of arsenic night and morning for 12 days. This is the amount for one horse. To give, mix in a small damp feed. Give the horses the best feed available. If possible, crushed oats, and if any green feed, e.g., lucerne, is obtainable, get it for them. Horses rarely get tuberculosis.

## THE RELATIVE BACON PRODUCING QUALITIES OF PIGS OF VARIOUS BREEDING.

[By W. R. BIRKS, B.Sc. (Agric.), Principal Roseworthy Agricultural College, and  
R. BAKER, R.D.A., Dairy Superintendent.]

### GENERAL REQUIREMENTS.

The lack of uniformity in type of pigs usually seen in our sale yards indicates a condition which will necessarily militate against the successful expansion of the pig-raising industry, especially if an extensive export trade is to be developed. The bacon curer is usually quite definite in his requirements as to type, and his ideas of a suitable carcass may be described briefly as one having the maximum length of side and depth of flank, a uniform and narrow layer of fat right along the back, ample development in thickness of flank, as even a distribution of lean amongst the fat as possible, fineness in the shoulder, a well-developed ham extending almost down to the hock, and a general firmness of carcass and fineness of bone. The careful breeder also, can very closely approach this ideal of bacon type, and to do this under South Australian conditions

View of Site—Roseworthy Agricultural College.

it is generally considered necessary to cross one of the large, long, narrow, and flat-sided breeds, namely, the Large White Yorkshire or Tamworth, with one of the stocky, quick-maturing types, Berkshire or Middle York.

The objects of the tests, which are described in this report, were, firstly, to draw public attention to the type of pig required by the trade and to determine which of the various types under test most nearly met those requirements; and also to test these types with respect to relative speed and economy of fattening by determining the length of time and the quantity of foodstuffs required in each case for development from weaner weights (say, 40lbs. to 60lbs.) to bacon weights (say, 160lbs. live weight).

The experiment was arranged and carried out at the suggestion and with the co-operation of, members of the Pig Breeders' Society and the Bacon Curers' Association.

For the purpose of the test weaner pigs were supplied by the following gentlemen:—Messrs. W. J. Aldridge, Gawler River; Urlwin and Bosisto, Gawler; E. A. Wilcox,

Gawler; S. J. Giles, Gawler; and Messrs. W. Jacobs Ltd., and Foggitt, Jones Pty. Ltd. undertook to do the slaughtering under proper supervision and also to cure the carcasses, and thus follow up the test to the bacon stage.

With the addition of weaners drawn from the College piggery, it was found possible to include in the test pigs of the following breeding:—Large White Yorkshire, Large White Yorkshire x Berkshire, Large White Yorkshire x Middle York, Large White Yorkshire x Gloucester Old Spot, Tamworth x Berkshire and Berkshire.

Large White York x Berkshire.

Unfortunately, only a pair of specimens of each type were available in some cases and the test pens were all limited in number, therefore, to two. Of these, moreover, in the case of the Large White Yorkshire x Gloucester Old Spot, one died from heat

Large White York.

apoplexy early in the test. It is recognised that from results obtained with such a limited number of animals there are possibilities of errors, which, in the circumstances, can be corrected only by repetition of the test later on as further specimens of the types in question become available.

Although the test was one of the relative fattening propensities of different types, relatively small differences only were ultimately recorded in this respect. Moreover, special care was devoted to the preparation of the foodstuffs, and the method of feeding, and before proceeding to the consideration of the comparative results of the test it is proposed to discuss the feeding and the average rate and economy of fattening of all the pigs under test.

#### *The Ration.*

The ration was determined upon largely as a result of previous tests, which appeared to indicate broadly the following requirements:—(1) An ample supply of food, practically as much as the pigs will take. (2) A high percentage of nitrogenous foodstuffs (that is, peas, meat meal, or milk) to provide a properly balanced ration. (3) An assured supply of vitamins, such as can be obtained by feeding green lucerne, meat meal, or milk. (4) An ample supply of mixed mineral compounds.

Pigs had also, under conditions of free choice feeding, shown a marked preference for wheat. Ultimately, therefore, the basal grain ration determined upon was made up thus:—Wheat, five parts; barley, two parts; peas, one part. For the morning feed the above mixture was fed along with skim milk at the rate of 4lbs. per pig in a

**Large White York x Gloucester Old Spot.**

separate receptacle. In the evening the same grain mixture was used with the addition of half part meat meal. The grains were all crushed, mixed with meat meal and mineral mixture, and the whole fed dry. The mineral complex was added at the rate of 1 per cent. of the grain mixture, and the ingredients were—Ground rock phosphate, 40 per cent.; salt, 20 per cent.; charcoal, 20 per cent.; Epsom salts, 5 per cent.; sulphate of iron, 5 per cent.; sulphur, 5 per cent.; bicarbonate of soda, 5 per cent. An ample supply of drinking water was provided at all times. The dry feed was supplied to each pen in quantities to suit the appetites of each type of pig. As far as possible all pigs were given as much as they would consume, and an accurate record was kept showing the daily consumption in each pen. Lucerne was supplied at the rate of 1½lbs. (green) per pig per day, and it was noticeable that the pigs almost always left their dry feed for the lucerne as soon as the latter was put in the sty.

An analysis of the actual constituents of the ration was made, with the results shown below:—

TABLE I.—*Showing Results of Analyses of Foodstuffs.*

|                 | Dry Matter. | Carbo-hydrates. | Fats. | Proteins. |
|-----------------|-------------|-----------------|-------|-----------|
| Wheat .....     | 91.7        | 70.4            | 1.3   | 16.2      |
| Barley .....    | 92.0        | 71.3            | 1.6   | 13.9      |
| Pease .....     | 92.7        | 57.1            | 1.5   | 26.9      |
| Meat Meal ..... | 95.1        | —               | 12.8  | 47.4      |
| Skim Milk ..... | 9.6         | 5.1             | .1    | 3.5       |
| Lucerne .....   | 26.1        | 11.7            | .9    | 4.6       |

In the proportion in which these constituents were fed the mean value of the nutritive ratio is 1 : 4, i.e., one part of protein to every four parts of carbo-hydrates, plus the equivalent starch value of the fats. This is a ration slightly richer in the nitrogenous protein material than is generally recommended, especially in the later stages. Thus, Wolff gives rations of the following nutritive ratios for the purposes stated, in "Feeding Standards":—

| Age.                 | Weight. | Total Dry Matter. | Digestible Nutrients. |                       |                  |
|----------------------|---------|-------------------|-----------------------|-----------------------|------------------|
|                      |         |                   | Protein.              | Carbo-hydrates & Fat. | Nutritive Ratio. |
|                      | lbs.    | lbs.              | lbs.                  | lbs.                  | lbs.             |
| 2 to 3 months .....  | 50      | 2.1               | 0.38                  | 1.50                  | 1 : 4            |
| 3 to 5 months .....  | 100     | 3.4               | 0.50                  | 2.50                  | 1 : 5            |
| 5 to 6 months .....  | 124     | 3.9               | 0.54                  | 2.96                  | 1 : 5.5          |
| 6 to 8 months .....  | 170     | 4.6               | 0.58                  | 3.47                  | 1 : 6            |
| 8 to 12 months ..... | 250     | 5.2               | 0.62                  | 4.05                  | 1 : 6.5          |

That the ration as fed in this test accurately met the requirements of the young growing pigs is indicated by the relatively small amount of foodstuff required to produce increase in live weight. Whereas it is usual to regard 4lbs. of dry foodstuff as essential for the production of 1lb. increase in the weight of a pig, in this test the mean results show that 3.36lbs. only suffice. This relation between the quantity of food consumed and increase in live weight is naturally a most important factor in the question of the cost of production.

In calculating the cost of the ration fed the following scale of prices has been adopted as representing approximately current rates:—

TABLE II.—*Schedule of Values of Foodstuff.*

|                       |                                               |
|-----------------------|-----------------------------------------------|
| Wheat .....           | 2s. per bushel = 40d. per lb.                 |
| Barley .....          | 1s. 6d. per bushel = 36d. per lb.             |
| Pease .....           | 3s. per bushel = 60d. per lb.                 |
| Meat Meal .....       | 17s. per cwt. = 1.82d. per lb.                |
| Skim Milk .....       | 2d. per gallon = 2.00d. per lb. (dry matter). |
| Lucerne .....         | 30s. per ton = 536d. per lb. (dry matter).    |
| Mineral Complex ..... | 8s. 6d. per 100 lbs. = 1.01d. per lb.         |

*Increase in Weight.*

The mean rate of consumption of dry matter in the whole ration per pig per day was 5.84lbs., and the mean cost of feeding 3.358d. per day. But the mean rate of increase in weight was 1.741lbs., so that the mean cost per pound of increase in live weight was 1.929d. The usual loss of weight in killing and dressing is 30 per cent., and this figure was closely approximated in the actual killing results in these tests. The mean cost of foodstuff per pound of pork, therefore, was 2.75d.

The pigs entered the test with a mean live weight of 55.91lbs. In eight weeks all but four had reached bacon weight (160lbs.), and these four were ready in 10 weeks from the commencement.

The mean results of the test may now be indicated in the form of a table.

TABLE III.—*Showing the Average Results from 11 Pigs, all Similarly Fed.*

|                                                               |             |
|---------------------------------------------------------------|-------------|
| Mean age at the commencement of test.....                     | 87.27 days  |
| Mean age at completion of test .....                          | 150.36 days |
| Mean weight at commencement of test .....                     | 55.91lbs.   |
| Mean weight at conclusion of test.....                        | 165.73lbs.  |
| Mean daily increase in live weight .....                      | 1.741lbs.   |
| Mean daily consumption of foodstuffs (dry matter).....        | 5.84lbs.    |
| Mean consumption of foodstuffs per lb. increase (live weight) | 3.36lbs.    |
| Mean cost of foodstuffs per lb. increase (live weight) .....  | 1.929d.     |
| Mean value per pound of dressed weight .....                  | 4.95d.      |
| Mean corresponding value per pound of live weight .....       | 3.46d.      |

The difference between the cost of foodstuffs and the value per pound live weight, namely, 1.53d., has, of course, to cover all other working and overhead expenses. It is difficult to estimate, even roughly, what these might be in any set of circumstances, but the figures appear to indicate that there is an ample margin and a satisfactory prospect in economic pig fattening so long as present relative prices are maintained.

*Relative Results.*

Turning now to the relative results from the different pens, the rates of increase in live weight and consumption of food, and the cost per pound increase, are shown in the next table. The figures in this and subsequent tables represent the mean results from two pigs in each pen, except in the case of the Large White Yorkshire x Gloucester Old Spot, in which a single result only was available.

TABLE IV.—*Showing Relative Rates of Fattening and the Cost per Pound of Increase in Live Weight of Pigs of Various Breeding.*

|                                        | Days in Test. | Initial Weight. | Final Weight. | Daily Increase. | Daily Food Consumption. | Food Consumed per lb. of Increase. | Cost of Foodstuff per lb. of Increase. |
|----------------------------------------|---------------|-----------------|---------------|-----------------|-------------------------|------------------------------------|----------------------------------------|
|                                        | Lbs.          | Lbs.            | Lbs.          | Lbs.            | Lbs.                    | Lbs.                               | Pence.                                 |
| Large White York .....                 | 58            | 63              | 163           | 1.707           | 6.04                    | 3.54                               | 2.02                                   |
| Large White York x Berkshire           | 58            | 54              | 165.5         | 1.922           | 6.10                    | 3.18                               | 1.80                                   |
| Large White York x Middle York         | 58            | 76.5            | 175           | 1.698           | 6.09                    | 3.59                               | 2.01                                   |
| Large White York x Gloucester Old Spot | 58            | 47              | 169           | 2.103           | 5.77                    | 2.74                               | 1.58                                   |
| Tamworth x Berkshire ....              | 72            | 46              | 160           | 1.583           | 5.54                    | 3.49                               | 2.03                                   |
| Berkshire .....                        | 72            | 44.5            | 164.5         | 1.666           | 5.60                    | 3.36                               | 1.95                                   |
| Means .....                            | —             | 55.91           | 165.73        | 1.741           | 5.84                    | 3.36                               | 1.929                                  |

As pointed out, owing to the limited number of animals employed in each case, the figures quoted in the tables can only be corrected by a repetition of the test on a larger scale; still, from the material available, it is possible to make the following comments:—On examination of the figures tabulated in Table IV., the Large White York. x Gloucester Old Spot, under the conditions of feeding and management employed, has shown a distinct tendency to lay on increase rapidly for a minimum of food consumed; in fact, 19 weeks from birth the pig reached bacon weight. On the other hand, though of the required weight, the food consumed appears to have been utilised for body increase, without showing the plumpness of a well-fed animal.

The Large White Yorks, on an average, were 22½ weeks before reaching maturity, they did not show the same economic use of food as the Large White York. x Gloucester Old Spot; still, they provided an even, well-filled carcass which more nearly approached the ideal animal.

The Large White York. x Berkshires quickly adapted themselves to sty feeding, and during the earlier weeks of the test rapidly increased in weight, in fact, at the end of five weeks they were showing a daily gain of over 2lbs. During the remainder of the test, in spite of an increased quantity of food, the rate of increase fell away.

Large White York x Middle York.

At bacon weight they presented a well rounded carcass, which had the appearance of being a little over fat. The age of this cross, at maturity, was 21 weeks.

The Large White York. x Middle Yorks provided the heaviest weights at the commencement of the test, but this did not appear to be an advantage, for the rate of fattening diminished as the test advanced. The two animals in this case were of opposite sex, and it was observed that the greater daily gain was recorded by the male, due mainly to the fact that the female lost ground when in season. Age at maturity was 21 weeks.

As referred to earlier in this report, it was necessary in the case of the Berkshires and Tamworth x Berkshires to prolong the fattening period by a fortnight in order to reach the required weights. It should be recorded that in all cases where Berkshire and Middle York. provided the whole, or part of the breeding the greatest daily gains were noticed during the earlier weeks of the test, and that towards maturity the rate of increase was reduced.

With regard to the comparatively low daily increase of the Tamworth x Berkshires this may be attributed to one of the animals meeting with an accident during the final week, reducing the daily gain for that period to .6lbs. With both the Berkshires and the Tamworth x Berkshires bacon weights were reached in 22 weeks.

The pigs were slaughtered under careful supervision, and the next tables show details of loss in weight in the process and the relative values of the carcasses. The grading was done by the factory experts, and the values shown were the actual prices paid by the factory as in the ordinary course of business.

TABLE V.—*Showing Relative Losses, in Slaughtering and Relative Values of Carcasses.*

|                                              | Farm Weight. | Factory Weight. | Loss in Transit. | Dressed Weight. | Cold Weight. | Loss in Slaughtering. | Total Loss. | Grading Order. | Price per Lb. |
|----------------------------------------------|--------------|-----------------|------------------|-----------------|--------------|-----------------------|-------------|----------------|---------------|
|                                              | Lbs.         | Lbs.            | Per cent.        | Lbs.            | Lbs.         | Per cent.             | Per cent.   |                | Pence.        |
| Large White Yorkshire .....                  | 162          | 149.5           | 7.71             | 114             | 111          | 25.73                 | 31.48       | 4              | 5             |
| Large White York x Berkshire .....           | 165.5        | 152.5           | 7.85             | 116             | 113          | 25.90                 | 31.72       | 5              | 5             |
| Large White York x Middle York .....         | 175          | 162.5           | 7.14             | 126             | 123.5        | 24.00                 | 29.43       | 2              | 5             |
| Large White York x Gloucester Old Spot ..... | 169          | 155             | 8.28             | 116             | 115          | 25.81                 | 32.54       | 6              | 4½            |
| Tamworth x Berkshire .....                   | 160          | 149.5           | 6.50             | 121.5           | 117          | 21.74                 | 26.88       | 1              | 5             |
| Berkshire .....                              | 164.5        | 152             | 7.60             | 122             | 118          | 22.36                 | 28.27       | 3              | 5             |
| Mean .....                                   | 165.73       | 153.36          | 7.46             | 119.54          | 116.36       | 24.13                 | 29.79       | —              | 4.95          |

It should be pointed out that both consignments of pigs encountered very hot weather and hence lost more weight in transit to factory than they might otherwise have done. On the other hand, the heat necessitated starving the pigs for 22 hours before forwarding, which would tend to give a low "farm" weight. The mean total percentage of loss was therefore probably normal.

*Financial Aspect.*

Results on the financial side can probably be better stated in a table showing results per carcass, thus:—

TABLE VI.—*Showing Financial Returns per Pig.*

|                                           | Increase in<br>Liveweight. | Value of<br>Increase. | Cost of<br>Food<br>Consumed. | Net Value<br>Increase of<br>per Pig<br>Over Cost<br>of Food. |
|-------------------------------------------|----------------------------|-----------------------|------------------------------|--------------------------------------------------------------|

The "value of increase," with one exception, is based on 5d. per pound dressed weight; in the case of the Large White York. x Gloucester Old Spot it was estimated at 4½d. per pound. Although there is an existing prejudice against the carcass of the Large White York. x Gloucester Old Spot as ideal from a bacon point of view, results in this test have shown that, owing to its ability to lay on increase economically, it

Berkshire.

has returned the greatest financial gains when bought over the scales at the price mentioned. On the other hand, when pigs of this type are offered for sale in the open market they generally sell at a greatly reduced value.

The following report on the condition of the carcasses, from a bacon point of view, was prepared by Messrs. S. Monks, representing Foggitt, Jones Pty. Ltd., and W. Jacobs, of the firm of W. Jacobs Ltd.

First consignment, consisting of two Large White Yorkshires, two Large White York. x Berkshires, two Large White York. x Mid. Yorks., and one Large White York. x Gloucester Old Spot.

1. Six out of the seven pigs under observation were described as conforming to the general trade requirements, i.e., first grade, while the Large White York. x Gloucester Old Spot did not possess the same well-defined characteristics, and was classed as second grade.

2. After scalding, each pig showed a somewhat red coloration on the skin, though not actually sunburn, was, in all probability, due to the excessive heat experienced during transit.

3. *Criticism of Carcass:*--

Large White York. x Mid. York (First Choice).—Sides: Of good length, lean, with light, even thickness of fat along the back. Middles: Well shaped, ribs well turned forming a good flank of even thickness. Hams: Fairly uniform in shape, though lacking fullness immediately above the hock. Shoulders: Well shaped and not too heavy. Bone: Light. Quality of flesh: Good appearance, soft texture in the flesh, fat and lean well balanced.

Large White York (Second Choice).—Sides: Of good length, well formed. Middles: Good, average thickness of fat along the back, well-turned ribs showing an even belly and flank. Hams: Long and light, rather tapering to the hocks. Shoulders: A tendency to over production of fat along the top. Bone: Fine. Quality of flesh: Soft in texture, with a slight predominance of fat throughout the meat.

Tamworth x Berkshire.

Large White York. x Berkshire (Third Choice).—Sides: Of good length, well formed. Middles: Well shaped, but showing an excess of fat along the back, ribs well sprung with good flanks. Hams: Well formed with desired plumpness, but showing a little too much fat. Shoulders: Heavy layer of fat along the top where not required. Bone: Fine. Quality of flesh: Of excellent texture, but showing too much fat throughout in comparison to lean.

Large White York. x Gloucester Old Spot (Fourth Choice).—Sides: Of good length, lacking uniformity. Middles: Lean, with moderate thickness of fat along the back, belly and flanks not well developed, losing weight where most desired. Hams: Lack plumpness, tapering sharply. Shoulders: Lean, but too heavy in the bone. Bone: Heavy, showing a thick hock. Quality of flesh: Below average in texture with coarse fibre, meat lean throughout.

Second consignment, consisting of two Tamworth x Berkshire and two Berkshires.

1. The four pigs of this consignment were classed as ideal from the trade point of view, and if curers could regularly obtain this class of article there would be no complaint. It should be pointed out, though ideal at the time of slaughtering, these pigs would quickly deteriorate if held at the farm for any further length of time.

2. After scalding the perfect condition of the skin of the Tamworth x Berkshire was most noticeable, whilst that of the Berkshire was little inferior. No evidence of the excessive heat was discernible, as in the case of the white pigs.

3. *Criticism of Carcass:—*

**Tamworth x Berkshire (Extra Choice).—**Sides: Of good length, lean, with perfect condition of fat along the back. Middles: Well shaped, ribs well sprung, forming an excellent flank. Hams: Well formed, plump, full at the hocks. Shoulders: Well shaped, with ideal proportions of fat to lean. Bone: Fine. Quality of meat: Good appearance, excellent texture, fat and lean well balanced.

**Berkshire (Choice).—**Sides: Of good length, with a uniform average thickness of fat along the back. Middles: Well shaped, showing even belly and flank. Hams: Well formed, plump, full at the hocks. Shoulders: Well formed, a trifle heavy at the top. Bone: Fine. Quality of flesh: Good appearance, fine texture, fat evenly distributed.

TABLE VII.—*Showing the Relative Losses Occurring in the Preparation of a Dressed Carcass for Curing.*

|                                        | Flare. | Head. | Backbone. | Feet. | Total. |
|----------------------------------------|--------|-------|-----------|-------|--------|
|                                        | Lbs.   | Lbs.  | Lbs.      | Lbs.  | Lbs.   |
| Large White York .....                 | 3-00   | 7-25  | 3-50      | 2-37  | 16-12  |
| Large White York x Berkshire ....      | 3-00   | 6-75  | 3-25      | 2-00  | 15-00  |
| Large White York x Middle York .       | 3-00   | 8-00  | 3-37      | 2-25  | 16-62  |
| Large White York x Gloucester Old Spot | 3-00   | 8-50  | 4-00      | 2-75  | 18-25  |
| Tamworth x Berkshire.....              | 4-00   | 8-50  | 2-50      | 1-75  | 16-75  |
| Berkshire .....                        | 3-50   | 8-00  | 2-50      | 1-75  | 15-75  |

Unfortunately, the weight of the flesh trimmed from the sides was not available, therefore it is not possible to estimate the total percentage of loss in the preparation for curing.

Indebtedness is acknowledged to Messrs. W. Jacobs Ltd. and Foggitt, Jones Pty., Ltd., especially Messrs. W. Jacobs and S. Monks, for the interest evinced in these experiments and for the valuable assistance given on all occasions in connection with the slaughtering of the pigs and the collection of useful data.

## ROSEWORTHY AGRICULTURAL COLLEGE.

## HARVEST REPORT, 1930-31.

[By W. R. BIRKS, B.Sc. (Agric.), Principal; T. A. COLE, D.D.A., Experimentalist; and L. W. BEAUMONT, R.D.A., Farm Superintendent.]

(Continued from page 758.)

## OATEN HARVEST.

Of the 400 odd acres of oats sown, 70 acres, in Crouch's A, was on fallow land, part of which had carried Sudan Grass in the previous summer. The yields there, but for the November gales, would have been excellent; as it was the Palestine, taken off beforehand, gave 12 bags per acre. Of the oats sown on stubble land about one-half (in Georges and Crouch's C.) partially failed and made indifferent ensilage and hay. The balance, including Nottle's A., Flett's C., and Daly's C. (the latter sown originally for greenfeed), gave a mean yield of under five bags per acre. Seeding had been at the average rate of 60bs. of seed and 1cwt. of superphosphate (45 per cent.) per acre.

The general results of the oaten harvest are shown in the next table, and the comparison with mean yields of previous seasons in the next.

TABLE XI.—*Summarising the 1930 Oat Returns.*

| 1930 .....              | 11.77     | 12.85  | 225.6  | 16 26           |
| Mean for 24 years ..... | —         | —      | —      | 22 2            |

The oat variety test plots were in a triplicate series similar to the wheat test plots. These were harvested during the rough weather in November, and certain anomalies in relative yields consequently crept in. Thus some varieties susceptible to wind damage, such as Sunrise, Kelsalls, and Lachlan, suffered severely, while later varieties, such as Algerian, though possibly carrying a lighter crop originally, were able to hold the grain better, owing to their tougher condition at the time of the storms.

The plot yields of the 16 varieties grown this season, together with all the recorded yields of these varieties back to 1925 are shown in the next table, along with their mean returns.

TABLE XIII.—*Showing Grain Yields of Varieties of Oats, 1925-30.*

| Sunrise x Mulga .....  | —     | —  | —     | —  | —     | —  | 30    | 24 | 13    | 32 | 9     | 31 | 18     | 2  |
| Imbros Island .....    | —     | —  | —     | —  | —     | —  | 18    | 30 | 12    | 39 | 22    | 10 | 18     | 0  |

Early Burt is thus apparently our best grain oat still, though both Palestine and Early Kherson are strong competitors, and for the period during which it has been grown (1927-30) Palestine has a higher mean yield.

In the next table are shown the mean grain and hay returns from the principal varieties of oats over various periods. The varieties are arranged in what appears to be their order of relative importance to us as dual purpose oats.

TABLE XIV.—*Showing Average Grain and Hay Yields of Certain Varieties of Oats.*

#### BARLEY HARVEST.

Barley was sown at the rate of 50lbs. of seed and 1cwt. of superphosphate per acre in Daly's B. (upwards of 50 acres) and the small Field No. 9. The latter was sown about the middle of May, was fed off lightly in July, and subsequently came away

clean and with just sufficient straw growth to carry a heavy crop. The Daly's B. crop was, perforce, sown earlier, germinated irregularly, and was more or less infested with weeds. It suffered more, too, from the November storms.

The results of the barley harvest, together with comparison with previous years' returns, are shown in the next two tables.

TABLE XV.—*Summarising the Barley Returns, 1930.*

| Field.                 | Variety.          | Area.  | Total Yield. | Yield per Acre. |
|------------------------|-------------------|--------|--------------|-----------------|
|                        |                   | Acres. | Bush. lbs.   | Bush. lbs.      |
| No. 9 .....            | Roseworthy Oregon | 5.885  | 191 40       | 32 30           |

| 1930 .....           | 11.77      | 12.85  | 57.2   | 16 48                   |
| Mean for 27 years .. | —          | —      | —      | 24 38                   |

The variety test plots, again in triplicate as with wheat and oats, included, this year, several imported types, which were tested at the request of maltsters. They proved, however, generally unsuitable for our conditions, chiefly on account of lateness of maturity. The recorded yields in these plots, however, are more or less misleading, as in the case of oats. Thus the figures for Roseworthy Oregon and Shorthhead (almost 12 bags and four bags respectively per acre) do not represent, by any means, the relative crops carried by these varieties prior to the storms, and, as in the case of oats, the later varieties were in a better condition to withstand the winds early in November and thus show up to better advantage than they might have done in more favorable harvesting weather.

The next table shows the details of the test plot results, together with whatever records are available, back as far as 1927.

TABLE XVII.—*Showing Grain Yields of Varieties of Barley Sown on Fallow Land, 1927-1930.*

## PEA HARVEST.

Pease were sown in two fields, Graingers A. and Flett's B., at the rate of 90lbs. of seed and 1cwt. of superphosphate per acre, on stubble ground. The varieties and areas sown were Early White Brunswick, 42 acres; and Early Dunn, 24 acres. Throughout the winter and early spring very good growth was made, and in September there seemed every prospect of a good return. The shortage of effective rain at that period, however, caused the pods to set on the small side. The usual attacks by grubs occurred towards the end of October and early November, though their effects were less marked in the Early White Brunswick than in the Early Dunn, which matured a couple of weeks later. Finally, the intermittent showers of November not only delayed harvesting, but also caused the pods to burst and scatter several bushels of grain per acre on the ground. Ultimately the Early White Brunswick returned 7bush. and the Early Dunn 2½bush. per acre. The average yield is represented by the relatively poor return of 5bush. 25lbs., and this is shown in comparison with the yields of previous seasons in the next table.

TABLE XVIII.—*Showing the Average Yield of Pease for Nine Seasons.*

| Season.                           | Rainfall.  |        | Area. | Average Yield per Acre. |

## HAY HARVEST.

Two small fields, Nos. 8 and 3a, were sown with similar series of test plots with wheat, oats, and hay mixtures. These paddocks had been fallowed and well worked, and the mean yields, approximately 36cwts. and 34cwts. per acre respectively, were

The two hay test fields, Nos. 8 and 3n, were sown in similar series of plots so as to provide duplicate results in order to minimise experimental error to a certain extent. The plots were about half an acre in area in No. 8 and one acre each in No. 3n, and the figures quoted in the next table are the mean results of the corresponding plots in the two fields. Varieties of wheat and oats were sown separately and in mixtures in these plots, and the details of the results are shown below.

TABLE XXI.—Showing Hay Yields Obtained from Wheat and Oats Sown Separately and as Mixed Crops.

| Crop.          | Variety.                        | Yield per Acre. |    |     | Mean Yield. |    |     |
|----------------|---------------------------------|-----------------|----|-----|-------------|----|-----|
|                |                                 | T.              | C. | L.  | T.          | C. | L.  |
| Wheat .....    | Crostan .....                   | 1               | 17 | 109 | 1           | 13 | 107 |
|                | Regal .....                     | 1               | 14 | 87  |             |    |     |
|                | Ford .....                      | 1               | 12 | 64  |             |    |     |
| Oats .....     | Galland's Hybrid .....          | 1               | 10 | 54  | 1           | 9  | 20  |
|                | Early Burt .....                | 1               | 16 | 75  |             |    |     |
|                | Early Kherson .....             | 1               | 14 | 98  |             |    |     |
|                | Sunrise .....                   | 1               | 5  | 73  |             |    |     |
|                | Lachlan .....                   | 0               | 19 | 56  |             |    |     |
| Mixtures ..... | Gallands Hybrid and Sunrise ... | 2               | 9  | 81  | 2           | 2  | 91  |
|                | Crostan and Early Kherson ....  | 2               | 3  | 61  |             |    |     |
|                | Ford and Early Burt .....       | 1               | 19 | 34  |             |    |     |
|                | Regal and Lachlan .....         | 1               | 18 | 76  |             |    |     |

It will be seen that the mixed crops have all given better returns than any of the wheats or oats sown alone. This is contrary to the results obtained in the last three seasons, but in close agreement with the mean results obtained in such experiments as this over a period of nine years. This comparison, and the average returns over the nine seasons, are shown in the next table.

TABLE XXII.—Showing Hay Returns from Wheat and Oats Sown Separately and as Mixed Crops, 1922-30.

| Season.                    | Wheat. |    |     | Oats. |    |     | Mixture. |    |     |

| 1930 .....                 | 1      | 13 | 107 | 1     | 9  | 20  | 2        | 2  | 91  |
| Means for nine years ..... | 1      | 17 | 44  | 1     | 15 | 14  | 2        | 0  | 97  |

For the purpose of comparing the relative hay yielding qualities of a number of wheat varieties, the returns from the best dozen hay wheats for the past four years are shown next. The figures for this purpose are now calculated from the returns of the hay cuts taken from the triplicate test plots already referred to, and thus represent the mean yield of three test plots in each case.

TABLE XXIII.—*Showing Hay Returns from the Principal Varieties of Hay Wheats, 1927-30.*

| Variety.                | 1927. |    |     | 1928. |    |     | 1929. |    |    | 1930. |    |     | Means. |    |     |

| Leak's Rust-proof ..... | 1     | 2  | 81  | 2     | 7  | 101 | 1     | 0  | 42 | 1     | 9  | 71  | 1      | 10 | 0   |
| Zealand Blue .....      | 1     | 7  | 89  | 2     | 2  | 15  | 0     | 16 | 80 | 1     | 10 | 104 | 1      | 9  | 44  |
| Huguenot .....          | —     | —  | —   | 2     | 6  | 99  | 0     | 18 | 48 | 1     | 10 | 89  | 1      | 12 | 4   |

The success of the relatively new wheats Sirdar and Crostan is again well illustrated in this table, although King's White maintains a very prominent position in the list. The other varieties, which show up well, are all fairly early and hardy, with the exception of Huguenot, which has done relatively well here, even under the hard conditions of the last few seasons.

The relative hay returns from all the oat varieties tested in recent years are shown in the next table.

The prominence of Early Burt, Early Kherson, and Sunrise, as dual purpose varieties, has already been indicated, and their predominance in mean hay yields is well shown above. Under the unusual conditions provided by dry spring and heavy rains in late October this year, however, some of the later varieties, *e.g.*, Warrigul, Guyra, Smyrna, have given better hay cuts. Even Imbros Island, usually altogether too late to mature properly here, has this year done better than our standard varieties. The character of the season, however, was so unusual that little importance is to be attached to these obviously anomalous relative yields of hay.

## ENSILAGE.

Whereas in normal seasons the crops set apart for ensilage purposes are usually ready to cut for this purpose towards the end of September, it was almost a month later this year before a start could be made with the work. Even the test plots in Ebsary's were, for the most part, too short and irregular in growth for cutting, and the attempt to record the relative yields of different types of ensilage crops had to be abandoned for this season. The best patches only in this field were taken for ensilage, giving about half a normal cut. Crouch's C. and George's were taken, perforce, as being the only considerable areas of crop ready at mid-October. The yields were very poor indeed, approximately a quarter crop, or the equivalent of half a ton of hay. A small amount of material was taken from the headlands of oats sown on fallow, and this was the only good cut of ensilage obtained, though still below normal.

The details of the returns are shown in the next table, and the usual comparison with previous years' records in the one following.

TABLE XXV.—*Summarising the Ensilage Returns, 1930.*

| 1930 .....                | 11.77      | 12.85  | 142.7  | 286          | 8  | 111 | 2               | 0  | 16  |
| Mean for 25 seasons ..... | —          | —      | —      | —            | —  | —   | 5               | 18 | 7   |

The per acre returns for this year have obviously been depressed by the inclusion of such a large area of indifferent oat crop, and, as the material taken from this area consisted largely of barley grass and other weeds, the quality was extremely poor. The mean yield, as shown on the records just over two tons per acre, is approximately one-third of the normal ensilage crop. It is the lowest average ensilage return recorded since 1919, and the fourth lowest in the recorded cropping history of the College farm. These facts further demonstrate the serious risk incurred in cropping on any but well-worked fallow land in a season such as that of 1930.

## INCREASED PRODUCTION.

*[An Address Delivered, by MR. F. COLEMAN, Chairman Advisory Board of Agriculture, at the Lyndoch Conference, February 26th, 1931.]*

I have been asked to address you this evening upon some "Phase of the Farmers' Problems." By this I understand some particular view of the question as to how the farmer and his family are to continue to live in reasonable comfort and independence.

Our natural sources of wealth are so restricted to the cultivation of the soil that the farmer, in the sense of being a primary producer, becomes of vital importance. Had South Australia coal fields, great mineral wealth, payable copper mines, natural timber supplies, rivers, waterfalls, or lakes at high altitudes like Tasmania, we could get reasonably cheap power, but, except the wind, South Australia has no sources of power as other States have, and so our secondary industries must of necessity be limited and cannot compete in importance with our primary ones. How, then, are we to develop our primary, and especially our export primary industries whose importance is so vital to our very existence?

I do not propose to discuss our wool industry, nor sheepfarming just now, important as they are, beyond pointing out that the export lamb trade is again claiming attention and is well worth exploring; there is a move in this direction and it deserves our best encouragement and practical support.

The wheatgrower is having a difficult and a lean time. I doubt if all the talk here and in other countries about orderly and controlled marketing is really helping us. Prices will, I am satisfied, improve, if for no other reason than that present prices are unremunerative. It is not possible to continue to grow wheat at 1s. 6d. to 2s. a bushel on the farm, and those who can will devote their land to other crops. At the same time I would strongly advise the wheatgrowers of South Australia to put under wheat as much as they possibly can, consistent with good wheatgrowing practice, this coming season, and to fallow a record area for next year's seeding in full faith that the returns will justify this course, and the State as a whole benefit.

The South Australian farmer has been mainly a wheatgrower. We cannot altogether blame him; he knows how to grow wheat, he has been brought up in a fairly hard school, but has learnt his lessons; he has had to contend with an inadequate and capricious rainfall, and over a large portion of this State with calcareous soils not naturally rich in phosphates. But our farmers have, in spite of adverse conditions, especially during recent years, produced their tale of wheat and at prices averaging 5s. 3d. at Port Adelaide. He has found wheatgrowing a profitable pursuit, not too exacting of his time, allowing of a spell occasionally in the autumn, possibly a fortnight's holiday, a chance to travel over the State, attend the Conferences of the Agricultural Bureau, thereby gaining knowledge of men and things, of shows with visits to the city or seaside. He has not felt the need of closer daily attention to the minor farm economies or production. There has not been the necessity to give attention to dairying for instance, and he has not troubled to raise calves, or pigs or poultry, but conditions have changed.

### THE DAIRYING INDUSTRY.

In the Lower North—the district this Conference of Bureaux represents—there are 4,420 holdings, on only 155 of which 10 cows or more are kept, and only on 106 of such farms is dairying the main source of income—that is less than 2½ per cent. Again, in this district there are only 814 cowkeepers with from five to nine cows, only 81 with from 10 to 14, and only 74 farmers with 15 cows or more. According to the Government Statistician there are 1,170 farms in this district on which no cows are to be found at all.

These figures are suggestive, and help to provide the answer to the question why South Australia in 1929 imported 1,697 tons of butter, valued at £296,983, and in 1930 imported 1,370 tons, valued at £239,820. Does anyone really think there is the need for us in this State to import over one-quarter of a million pounds' worth of butter a year from the Eastern States? Surely there is not.

I am not advocating dairying for all our farmers in the Lower North district, but surely 3½ per cent. of the farms with 10 cows or over is a ridiculous proportion. Out of over 4,000 holdings we might look for one-tenth at least carrying 10 cows or over. And these times call for the fullest development of our holdings, and especially greater production where there is a small margin of remuneration.

In this district, including such country as that between Riverton and Clare and out towards the Hayleton and Blyth plains, and again round Lyndoch and Gawler, we have good land, a reliable and adequate rainfall, and a suitable climate for dairying. Outside these favored districts we find such country as at Eudunda, open, undulating, with but 17in. rainfall, yet round Eudunda there are eight or ten farmers who have given the dairy cow a fair chance, and the cow has responded to that attention as she always will. I made it my business to visit eight of those farms last spring, and was told that but for the cows the farmers would not have been able to carry on in some cases. That was last year. I do not know what sort of crops they harvested this season, but we all know that the feeble price for wheat would return very little, if any, beyond the cost of cropping. I feel sure that those who have cows are much better off than those who have no dairy cattle.

*I challenge any farmer present here to show that the Eudunda district is more adapted to dairying than the average of the Lower North. What has been and is being done at Eudunda to-day by a few practical men can, I am sure, be done in many places in this Lower North Conference District, where the conditions are certainly better, because there is heavier rainfall, and on the whole probably better climatic conditions.*

I am, of course, aware that to stock up a farm with good dairy cows at the present time is not a practical proposition; good cows are difficult to obtain. They would be expensive and cash is very scarce. But are we making the best of such stock as we have? Are we rearing the best heifer calves? Are we feeding such cows as we may have to the best advantage. We need not grudge giving our cows good chaffed hay. The days when the cows were turned out after milking into a bare paddock or among stinkwort are, I hope, past. At present price of hay in this district it will certainly pay to feed to dairy cows, and bran at £3 15s. to £4 a ton is not too dear a concentrate with butter fat at 1s. 4d. a pound. Are we who keep cows trying to improve our dairy cattle? Are we doing our best by the use of sires from heavy milking and butter production strain to breed heifers that will be better producers than their mothers? Do we pay attention to what is termed a balanced ration, by which we mean that the feed supplied to our milch cows shall be such that full nutritive value will be used by the cow, that the albuminoid ratio—that is, the proportion of flesh forming to fat producing material is such that the food is used to the best advantage, and no portion wasted. The ideal proportion or ration is that of our natural spring pasture just as the grasses are coming into flower. At that time the cattle are sleek, in splendid condition, and at the peak of production, the ratio is about 1 to 5 of albuminoids or flesh-forming material to carbohydrates or fats. At this time of the year when the grazing is poor, the grass dry and fibrous, and lost its flavor and quality, it is necessary to feed by hand, and to supply enough bulk to fill the cow's paunch for adequate digestion and at the same time concentrates to supply a ratio of 1 to 5 so that she will continue to produce milk. If the ratio is much greater, say 1 to 15 or 1 to 20, some of the food is not fully used and is wasted, we need to feed economically.

The following are some examples of balanced rations. The quantity can, of course, be adjusted to the requirements of the individual cow, and the amount of roughage or pasture obtainable.

For a cow giving 3 gallons of milk a day: Wheaten hay chaff, 20lbs.; bran, 4lbs.; and meat meal, 2lbs.; or oaten chaff, 20lbs.; crushed oats, 4lbs.; meat meal, 2lbs.

For a cow giving 4 gallons: Wheaten hay chaff, 20lbs.; crushed oats, 4lbs.; bran, 4lbs.; and meat meal, 2lbs.

For a cow giving 3 gallons to 4 gallons: Oaten hay chaff, 20lbs.; bran, 4lbs.; crushed oats, 4lbs.

#### DAIRYING AT EUDUNDA.

In the Eudunda district last spring the average return from seven farmers was £24 5s. per cow per year; individual returns by some of the farmers averaged from £20 to £31 per cow. This is a better average per cow than that of my cows and heifers, which works out at about £16 per cow per year during the past 10 years. This year it looks like £15 per head. You will probably be able to figure out what it costs per year for grazing and additional hand-feeding necessary to keep your milch cattle in good condition and profit. I think that at £10 per head you would be getting a better price for your wheaten or oaten hay and your oats than you can get by marketing them in the usual way in the open market. The balance or profit over the cost of feeding of £5 or perhaps £10 a cow is not unduly high; this is what you get for the trouble and labor of looking after and milking your cow. The cash fortnightly from the cream factory will be very welcome, and go a long way towards paying the local store for groceries, &c. I am pretty sure those Eudunda farmers, some of them dependent for a living upon the returns from their cows, would reckon £10 at least beyond all cost of feeding and outlay other than their labor.

#### GREEN FODDERS AND ENSILAGE.

Since successful dairying depends so much on liberal as well as judicious feeding, it is necessary to plan ahead and put in a few acres of barley or oats for early green feed or grazing. Later in the spring, when feed is plentiful, and just before hay-cutting commences, cut some green stuff and put it in a pit or hole, such as an old disused underground tank or cellar, cover with straw or bags to exclude the air, and

# Scientific Farming!

**THAT** is the only proper response to present troubles—**THAT** is the road to solvency and restored prosperity. . .

Economies are necessary, but to cut the application of super in this years farming effort would be a fatal mistake. .

Science and Economy dictate the liberal use of

45% Super

[DATON]

weight it down heavily with dirt or fencing posts, or both. If the air is well excluded, the green crop good fodder, and it is well pressed down, the silage will turn out well, and prove very useful for the cows during the late summer or autumn when only dry feed is otherwise available.

Between the 12th and 18th November last I put about 8 tons of green wheaten and oaten hay into a hole 18ft. x 8ft. x 4ft. 6in. that had been dug out not far from the milking shed. This was opened on January 1st, and there was very little loss—less than 6in. round the sides and on top. It had been covered with wild artichokes, then the earth from the hole was heaped on top. This little pit has again been filled with maize and is still full of maize silage. The maize was drilled in on fallow in October, when we had nearly 4ins. of rain.

Less than 1½ins. has fallen since, yet without any irrigation or watering beyond the little rain referred to, the crop grew about 3ft. 6ins. to 4ft., and provided a good cutting for the cows during January, and some 9 tons has been chaffed into the pit.

Of course, a properly built silo is the correct way of preserving fodder for times of scarcity, but as a temporary means to get silage these holes dug out do answer the purpose to some extent. In some cases I understand the pit has been scooped out with a scoop and horses or tractor, then when filled, the earth taken out is again scooped on top, and this has proved quite satisfactory, with very little loss. Succulent food is very helpful for milch cattle, and though involving a little more labor in handling, is worth while, and I recommend farmers to try putting some of their green crop into silage next spring.

We should use much more butter and dairy produce than we do. In New South Wales the consumption two years ago was 35lbs. per head, while South Australia only uses 23lbs. and Australia 29lbs. It is claimed that local consumption should reach 87,000 tons, and it might be raised to 100,000 tons, if more attention was devoted to home markets. In any case there is room for greater production in South Australia.

#### ESSENTIAL POINTS SUMMARISED.

I repeat the points I have brought forward:—

*Conservation of Fodder.*—Can you imagine a business man starting some manufacturing enterprise without considering and providing for his raw material, the efficiency of his machinery, and the quality of his finished product? So with dairying we must provide the food, the cows, and conveniences for the milk and cream.

*Improve pasture* by top dressing, and provide for additional feed during late autumn and winter, when cattle need more feed to keep up the animal heat in addition to providing milk. Replace grass pastures with minerals taken.

*Test the cows* to see which are worth keeping and feeding. With Jerseys 400lbs. butter fat should be aimed at, and an average of 300lbs. ought to be reached, and I think that 250lbs. in the spring and summer lactation is better than the same quantity in winter, for though values are higher, it takes extra feeding to maintain condition, warmth, &c.

*Put down some Silage;* it will keep indefinitely, free from vermin, will not burn, hence no fire risk, and is a very essential roughage for dairy cattle.

*Provide shelter* for livestock; this will save food and afford comfort for the cows in winter.

*Rear the best calves* and give them the best attention.

*Care for the cream.* As the milk comes from the cow it is, generally speaking, quite right. Of course, certain weeds will flavor it, but as a rule the milk is good; the after treatment is responsible for the loss of quality, and there is a great deal too much second quality cream sent to the factories.

Associated closely with dairying are pigs, and at present prices for grain it will pay to feed wheat with milk to pigs; 7lbs. skim milk and 4½lbs. grain for pig feeding is a well-recognised ratio, and an economical one to use.

## • WHITE OIL SPRAY AND MANURING OF APRICOT TREES.

[By Mr. J. B. HARRIS, District Horticultural Instructor.]

Following upon experimental work with summer oil sprays carried out at the State Experimental Orchard during 1927-28 season, it was decided that experimental spraying with white oil be carried out in the orchard of Messrs. S. and L. Plush, under supervision, so far as possible, of the local Horticultural Instructor. Messrs. P. and F. Warnecke (Nuriootpa) and F. H. Lock (Angaston) also used white oil fairly extensively to combat codlin and other pests during the past season, and later in this paper reference is made to some of their observations.

### TESTS AT LIGHT'S PASS.

For purposes of comparison, results from three plots—A, B, and C—are given, each plot consisting of 10 trees. Each plot received five sprayings during the past season, the dates of spraying being October 18th, November 4th, December 4th, December 23rd, and January 25th. Plots A and C were each sprayed five times with arsenate of lead mixed as 1lb. of paste to 15galls. of water. Plot B's five sprayings were—First, 1lb. arsenate of lead to 15galls. of water; second, 1gall. alboleum in 50galls. water; third, arsenate of lead 1.15 plus alboleum 1.50; fourth, 1gall. alboleum in 50galls. water; and fifth, 1gall. alboleum in 50galls. water. Plots B and C are alongside each other, plot C being the one on which molasses trapping tests have been carried out during the past four years. Plot B may have derived some slight benefit from this trapping; plot C almost certainly has. Plot A is a check, or comparative plot, in another part of the orchard. All the trees have been bandaged, and the grubs in bandages destroyed periodically.

Plot A, the comparative plot, sprayed with arsenate of lead only, picked 46 cases of apples, of which 26 cases, or 56 per cent., were codlin infested. Plot B, oil and lead arsenate sprayed, picked 69 cases of apples, of which eight cases, or 11 per cent., were codlin infested. Plot C, with five lead-arsenate sprayings and molasses traps, picked 78 cases of apples, of which 25, or 32 per cent., were codlin infested.

It has been suggested that plot A, sprayed with arsenate of lead only, owing to its situation in the orchard, does not provide a fair standard for comparison with plot B, which was sprayed with oil and arsenate of lead. Without further discussing that point, let us compare plots B and C, which are situated alongside each other in the

same block of trees. Plot C, with five arsenate sprayings, had the advantage of a molasses bait trap in each tree, and experience of the past four years has indicated that these traps are definitely helpful in producing a greater percentage of clean fruit. Plot B, oil and arsenate sprayed, had no such advantage, but produced 21 per cent. more clean fruit than plot C. Taking the average crop from plots B and C as 73½ cases, the proportionate increase from plot B is rather more than 15 cases, or 1½ cases per tree.

The cost of spray material per tree, allowing 2 galls. of spray per tree, each spraying was—Plot C, approximately 6½d. per tree for the season; and plot B, arsenate and oil combination, approximately 3d. for the arsenate of lead at 10d. lb., and approximately 1s. for alboleum at 7s. 6d. per gallon, or 1s. 3d. per tree. Therefore the increased cost of spray, using alboleum and arsenate combined, is 8½d. a tree, whilst value of the increased quantity of clean fruit in this case was 6s. per tree.

This merely embodies results of one season's test carried out on 20 trees, and although the results should not be taken as conclusive, they should encourage further investigation by practical growers in addition to further experiments along these lines. Dr. Pettey, Entomologist to the Department of Agriculture in South Africa, has drawn attention in a recent bulletin to the danger of fruit being damaged by summer oil sprays. The characteristic damage of which he speaks—a discoloration of the skin in vicinity of the calyx—has been noticed only on certain varieties in South Africa, and in this district has been found only on Strawberry Pippin apples in Mr. Lock's orchard, although Rome Beauties, Northern Spys, Jonathans, and Dunn's Seedlings were also sprayed with white oil. Messrs. Warnecke Bros. concentrated their applications of white oil on portions of their orchard where woolly aphid and red spider were prevalent. Control of these pests, as of codlin, is stated to have been satisfactory.

#### MANURIAL TESTS WITH APRICOT TREES AT LIGHT'S PASS, 1929 AND 1930.

A test to determine, so far as possible, the effect of superphosphate applied to apricot trees was commenced in the orchard of Messrs. S. and L. Plush, Light's Pass, in September, 1928. The block selected is situated alongside the road running from Plush's corner to Stockwell, and consists of 56 trees about 15 years old, the trees being approximately the same in size, vigor, and general cropping capacity. The soil, which shows very little surface variation throughout the block, is a red, sandy loam. To provide a basis for comparison, the plots were set out so that certain groups of trees were left unmanured, and between manured and unmanured groups, rows of barrier trees were left to utilise any dissolved fertilizer which might flow in a lateral direction from the manured to the "check" or unmanured plot.

The row at the northerly end of the block was eliminated from the test in consideration of the advantage which is frequently seen in an outside row where trees meet competition from one side only. At this juncture Mr. Harris displayed a plan of the plots, showing the 20 manured trees for comparison with 15 check trees; results being derived from an average of the trees treated. This plan was adopted to admit of manuring the maximum number of trees while maintaining the necessary barrier rows and check plots. All manures applied have been broadcast by hand on an area corresponding roughly with spread of the branches of the tree to which manure was being applied; the manures being immediately harrowed in.

The first application was 6lbs. of superphosphate, 45 per cent. W.S.P., made on September 20th, 1928. Good cultivation was maintained throughout the season, which was exceptionally dry. Manured trees ripened the bulk of their fruit rather earlier than unmanured trees. The 20 trees which received application of 6lbs. 45 per cent. W.S.P. on September 20th, 1928, produced in January, 1929, 53½ cases of fruit; an average of 2.675 cases per tree. The 15 trees not manured produced in January, 1929, 43 cases of fruit; an average of 2.866 cases per tree. The manured trees thus produced approximately 12lbs. per tree less fruit than those not manured.

The test was continued during 1929-30 season, but a variation was made on the manured plot which contains eight trees by addition of sulphate of ammonia at the rate of 2lbs. per tree to each of the eight trees. It was considered, after experience of the previous year, that 12 trees treated with super only would sufficiently indicate the effect of that manure, and the eight trees treated with super and sulphate of ammonia would indicate the influence of the latter. All the manured trees received 6lbs. of 45 per cent. W.S.P. on August 30th, 1929; the eight trees in the smaller plot receiving 2lbs. sulphate of ammonia per tree on October 7th, 1929. Quantities of fruit harvested from the plots were:—12 trees, with super only, produced 47 cases, or 3.916 cases per tree; 15 trees, with no manure, produced 62½ cases, or 4.166 cases per tree; eight trees, with super and sulphate of ammonia, produced 35½ cases, or 4.437 cases per tree. Expressed in another form, on the basis of 54lbs. of fruit per case:—Trees which received super only produced an average of 211lbs. 8ozs. per tree; trees which received no manure produced an average of 225lbs. per tree; and trees which received super and sulphate of ammonia produced an average of 239lbs. 10ozs. per tree.

Experience of the past two seasons tends to show that these apricot trees do not benefit by addition of super alone. Sulphate of ammonia and super used in conjunction have given an increase during the past season, when tested on eight trees, of approximately half a case (28lbs. 2ozs. exactly) of fruit per tree over trees manured with super only, and an increase of 14lbs. 10ozs. over trees which received no manure. Results so far obtained in this test are not intended to be conclusive. The test is being continued, but results so far obtained may be of interest and serve as a guide to others in this district who are interested in manuring of apricot trees.

Further orchard experiments which are being conducted under auspices of Bureau Branches in this district relate to codlin moth trapping, manuring of apple trees with sulphate of ammonia, and a pruning test on apricot trees which has been instituted by the Chief Horticultural Instructor.

Mr. F. L. Johnson's garden at Wudinna, Eyre's Peninsula. This garden contains a large collection of fruit trees, amongst which there are many new varieties.

# FERTILISERS ACT, 1918—ANALYSES OF FERTILISERS.

Following are results of Analyses obtained by the Government Agricultural Analysts from samples procured and supplied during the year ended December 31st, 1930.

NOTE.—Deficiencies greater than permitted under Section 12 of the Act are shown in *bold type*.

| Sample No. | Name of Firm and Fertiliser.                | Phosphate.          |                     |                     |                     |                     |                     | Nitrogen.           |                     | Nitrogen as Nitrates. |                     |

## ORCHARD NOTES FOR SOUTHERN DISTRICTS FOR MARCH.

[By CHAS. H. BEAUMONT, District Horticultural Instructor.]

Packing apples and pears for export or for storage will be the principal work of the month; unfortunately, there will be but little for export as compared with last year, but the same need of care is here. Fruit which has not begun to mature will not store or carry well, and damaged fruit will get worse and ruin the sample.

Drying of grape fruits will continue; growers must resist the tendency to pick too soon; matured fruits are necessary to make good dried produce.

If it is intended to extend the orchard or vineyard, or to plant a new one, the soil should be kept in good order, free of weeds, and finely cultivated. For trees it is a good practice to open up the holes early, and stakes can be put into position. Order at once from the nurseryman so as to be sure of getting the varieties required.

Citrus trees may be planted this month; be sure and have all trees fumigated before being sent on; it is very easy to introduce pests into the orchard, but it is very difficult to control them afterwards.

Fumigation for scale insects should be proceeded with at once. It is the best method we have so far for controlling these pests, but it is not by any means a perfect process, as many insects have a means of resistance. Where it is not practicable to fumigate, the use of white oil sprays is advised—Volek and Alboleum do good work if used thoroughly; do not use any spray on hot, sunny days.

As a preventive of "brown rot," limbs of citrus should be kept up from ground.

Almond gathering will be in full swing, and care should be taken to keep the varieties separate; mixed lots bring lower prices. Cracking by hand is a tedious process, but several machines are under trial, and later on some simple machine may be obtainable which will do the work expeditiously and with little damage to the kernels. Hardshells should pay to crack, and mostly they have the small kernels which are required by the manufacturers.

## THE AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

### CONFERENCE AT LYNDOK.

The first of the 1931 series of Conferences of the Agricultural Bureau was held on February 26th, when Branches in the Lower North district met at Lyndoch. The Department of Agriculture was represented by Messrs. F. Coleman (Chairman), A. M. Dawkins (member Advisory Board of Agriculture), Prof. Arthur J. Perkins (Director of Agriculture), G. Quinn (Chief Horticultural Instructor), H. B. Barlow (Chief Dairy Instructor), A. H. Robin, B.V.Sc. (Government Veterinary Officer), R. C. Scott (Superintendent Experimental Work), C. F. Anderson (Government Poultry Expert), W. C. Johnston and J. B. Harris (District Instructors), H. C. Pritchard (General Secretary), and F. C. Richards (Assistant Secretary Agricultural Bureau).

There was an excellent attendance of delegates from the Rosedale, Williamstown, Lyndoch, Light's Pass, Roseworthy, Lone Pine, Wasleys, Saddleworth, Gawler River, Greenock, Wirrilla, Clare, and Truro Branches. A feature of the Conference was the

excellent exhibit of farm produce, which included fresh, preserved, and dried fruits, cereals, hay, ensilage, vegetables, and cut flowers staged by the members of the Williamstown and Lyndoch Branches. Mr. A. Springbett (Lyndoch) presided and the opening address was delivered by Mr. F. Coleman.

During the course of the Conference, officers of the Department replied to a large number of questions, and the following papers were read and discussed:—"Haymaking," Mr. R. Nietschke (Truro); "Sheep and Wool," Mr. W. Scott (Truro); "Mixed Farming," Mr. G. Buckby (Wasleys). It was decided that the 1932 Conference should be held at Owen. Mr. A. M. Dawkins presented the trophies to the successful competitors in the district crop competitions:—Midlands—First, R. J. Clift; second, A. G. Blyth; third, A. J. Melrose; fourth, G. M. Frost. Central—First, T. W. Roenfeldt; second, A. J. Siedel; and best crop entered by a member of the Wasleys Branch, W. K. Oliver.

During the evening session Mr. F. Coleman addressed the Conference on the subject, "A Phase of the Farmers' Problems," and Mr. C. F. Anderson spoke on "The Housing and Feeding of Poultry."

Special sessions were held for the delegates from Women's Branches. Mrs. J. Hammatt (Williamstown) presided. There was a very good attendance of delegates, and the following papers were read:—"Butter Making," Mrs. A. Nottle (Wasleys); "Dried Fruit," Miss L. Dennison (Auburn); "Gelatine," Mrs. S. Schunke (Wirrilla); "A Chaff, Hay, or Fuelless Cooker," Mrs. M. Wild (Williamstown); "Fancy Work," Miss G. George (Wasleys). Miss E. Campbell, Dip. Dom. Econ., of the Education Department, gave an instructive address, "The Use of Hessian in the Home."

### **METTER'S "NUOIL" DOUBLE GEARED SELF-OILING WINDMILLS.**

**IN SIZES FROM 6ft. TO 14ft. WHEEL.**

The strongest, best lubricated, best designed, and best governed.  
Pump more water on a lighter boom.

No spring on automatic oiling system to break, and no sheet-metal oil conveyors to wear out.

Gained First Prize and Silver Medal Adelaide Show, 1922, 1923, 1924, 1925, 1926, and 1929 (no entry 1928-29).

Also Gold Medal at the All-Australian Exhibition, 1920.

A reliable and useful investment, and the popular choice of experienced pastoralists, farmers, and others.

#### **METTER'S 5ft. "MINOR" WINDMILLS.**

Most efficient for pumping water from shallow depths.

**MILL ONLY, 29 15/0; on 15ft. G.I. TOWER, £15 15/0; on 20ft. TOWER, £17 17/6.**

#### **METTER'S FUEL STOVES and WASHING COPPERS.**

Use less fuel and retain heat longer.

**WHOLLY MANUFACTURED IN SOUTH AUSTRALIA BY**

## **METTERS LIMITED,**

**98, 99, 100, North Terrace,  
ADELAIDE.**

**"NO FEAR OF A DROUGHT WITH A  
METTERS ABOUT."**

## ADVISORY BOARD OF AGRICULTURE.

---

The monthly meeting of the Advisory Board of Agriculture was held at the Blackwood Experimental Orchard on February 25th, there being present:—Messrs. F. Coleman (Chairman), H. N. Wicks (Vice-Chairman), G. Jeffrey, A. M. Dawkins, P. H. Jones, S. Shepherd, A. J. Cooke, A. L. McEwin, P. J. Baily, Dr. A. E. V. Richardson (Director Waite Research Institute), G. Quinn (Government Horticultural Instructor), R. Fowler (Manager Blackwood Orchard), and H. C. Pritchard (Secretary). Apologies were received from Messrs. R. H. Martin, J. W. Sandford, H. S. Taylor, Prof. A. J. Perkins, and Mr. W. R. Birks.

*Agents' Commission on Superphosphate.*—A communication was received from the secretary of the Superphosphate Association following an interview with a committee appointed by the Board to interview the association with regard to commission paid to agents for orders for superphosphates. In the course of his reply, the secretary to the association states that the manufacturers for many years have sold their products through the intervention of certain distributing firms, two of whom were so dissatisfied with their experience of this particular business that they have withdrawn entirely from this trade; it did not pay them to continue, even at the rate of commission which has been suggested as excessive. The selling price has always been based on an all-round figure averaged to provide for the credit which has had to be given, and if, as suggested by the Advisory Board, it were possible for certain farmers, i.e., the more affluent ones, to deal direct for cash, the effect would be that the remainder, who were in a less flourishing condition, would have to pay more to bring out the average, for the net return to the manufacturer is not capable of reduction, being based upon a figure that barely gives an adequate return to the shareholder. If all the affluent farmers came direct, that would leave all the poorer "marks" to be carried by the distributors, who naturally would need a higher commission to compensate for this risk. Much has been said about the unnecessary employment of agents, who are paid 2s. 6d. per ton for his services. An agent's duties consist in soliciting orders, advising his principals upon the financial standing of the client, endeavoring to aggregate orders to make up full truck loads, keeping an eye on consignments which arrive and may require sheeting, &c., after arrival, and helping in collection of accounts. That is quite a sheaf of duties, and it is a fact that in the Victorian instance, where the services of an agent are not provided, the customer frequently is in such a quandary that were it not for the good offices of an agent of one of the other manufacturers who, without remuneration (but possibly in the hope of benefits to come), saves the customer from expense such as demurrage, unloading trucks, &c., such farmer would be at considerable financial loss. It would be impossible to reduce the price of superphosphate by the elimination of the distributors, for if that were done, the price would have to be increased to compensate for the extra financial burden.

Members expressed their appreciation of the work performed by the committee in this matter.

*Leave of Absence.*—Mr. J. W. Sandford, who has been appointed by the Government as a member of a committee to inquire into education in South Australia, applied for leave of absence from the Board until such time as his duties with this committee expired. The Secretary was instructed to request the Minister to grant such leave of absence to Mr. Sandford.

*Life Membership.*—Life membership of the Agricultural Bureau was conferred upon Messrs. G. A. Bennett and W. J. Hemming of the Kalangadoo Branch. The Kalangadoo Branch also made application for Mr. N. McCall to be made a life member. In this case, however, office records showed that Mr. McCall had only been associated with the Bureau for 17 years. The Secretary was given authority to issue the certificate pro-

vided that the Branch could first of all furnish additional information showing that Mr. McCall had 20 years' membership to his credit.

*New Members.*—The following names were added to the rolls of existing Branches:—Springton—B. H. Greatz; Monarto South—E. H. Thiele, T. Peake; Wepowie—J. M. Jasper; Caltowie—J. H. Woolcock, G. Amey, — Neindorf, — Neindorf (Bros.), J. Doody, A. Crossman; Millicent—H. C. Godson; Paskeville—C. Lee, E. A. W. Zimmermann, H. C. J. Daniel; Auburn Women's—Miss B. Dennison; Warcowie Women's—Miss M. M. Sweet, Mrs. A. G. Avery, Mrs. E. A. Wheadon; Bowhill—A. Loechel; Caltowie—A. Travers; Parilla—S. A. Leane; Wolseley—W. D. M. Starick; Hartley—H. C. Brook, R. H. Cross; Virginia—John Bowman; Goode Women's—Miss Hilda Linke, Miss D. Tucker; Wirrabara—A. J. Watt, G. Kranz, W. Freeman, E. A. W. Harding; Wandearah—E. H. O'Shaughnessy. Number of new members for approval, 32; number of members on January 28th, 1931, 8,426; number of Branches, 305.

**Buy your Vegetables  
with your Groceries  
in packets!**

WHEN next you make up your list of provisions to be bought, add to it Swallow & Ariell's Compressed Vegetables. They are easily prepared—economical—with the true vegetable flavour. Though only water is removed from them they have but a tenth the weight of fresh vegetables. Compressed Vegetables are easily carried, and as easily stored.

Carrots, Parsnips, Turnips, Onions, and mixed—in ½-lb. cartons and 1-lb. tins. Tomatoes and Rhubarb—in ½-lb. cartons. Beetroot—Loose, in 1-lb. tins. Mixed Vegetables—Loose, in 1½-oz. packets.

Ask your Storekeeper for:

*Swallow & Ariell's*  
**COMPRESSED  
VEGETABLES**

## DAIRY AND FARM PRODUCE MARKETS.

A. W. SANDFORD & Co., LIMITED, reported:—

**BUTTER.**—The demand for all grades of butter has kept up fairly well considering the times, and so far production in this State has been almost sufficient for all requirements. The quantities are now falling back, however, so that it will be necessary to import increased supplies from the eastern States from this out. Owing to the exchange position, the buyers for London have not been operating quite so freely throughout Australia and f.o.b. values have weakened. The present prices are as follows:—Choicest creamery fresh butter, in bulk, 1s. 7½d.; prints and delivery extra; second and third grades, 1s. 5½d. (These prices are subject to the stabilisation levies). Best separators, 1s. 3½d. to 1s. 4½d.; well conditioned store and collectors', 1s. to 1s. 1d.; heated and pastry, 11d. per lb.

**EGGS.**—As usual at this time of the year, eggs are declining each week, but farmers are retaining the laying hens more so than usual so as to obtain an earning from the eggs produced, and production is therefore keeping up better than it did last year. Values hardened towards the latter end of February, but with Sydney and Melbourne markets weaker, it is preventing rates here moving higher for the time being. Ordinary country eggs, 7½d. per dozen; duck, 8½d. per dozen; selected, tested, and infertile, higher.

**CHEESE.**—The supplies of milk to the cheese factories are now considerably reduced, and therefore the production of cheese is declining each week. With the higher prices ruling for butter, cheese firmed in sympathy, and rates at present are:—New makes, large to loaf, 8½d. to 8½d. per lb.; semi-matured and matured, 11d. to 1s. per lb.

**ALMONDS.**—Values for the time being are only nominal, and there are very few inquiries for parcel lots at present, and only just odd bags are selling from day to day. There are increasing quantities arriving each week of the new crop, and large buyers are holding off because of the almonds not being thoroughly dried, and there is always at this time of the year a considerable shrinkage in weight. Brandis, 7d. to 7½d.; mixed softshells, 6½d. to 6½d.; hardshells, 4d. to 4½d.; kernels, 1s. 6½d. to 1s. 7d. per lb.

**HONEY.**—Although the "take" this year seems likely to be a short one, there are ample stocks held from the previous season, and trade is only moderate for prime clear extracted lines, whilst lower grades are neglected. Prime clear extracted, in liquid condition, 3½d. to 3½d. per lb.; best quality candied lots, 2½d. to 3½d.; second grade, 1½d. to 2d. per lb.

**BEESWAX.**—Moderate supplies; demand fair; 1s. 4d. to 1s. 4½d. per lb., according to quality.

**BACON.**—The demand for bacon is fairly good, but until the winter season comes in the turnover will not improve to any great extent. Supplies marketed were ample for all requirements. Best local sides, 9½d. to 10d.; best local factory cured middles, 8½d. to 9d.; large, 7½d.; local rolls, 8½d. to 9d.; Geo. Farmer's "Sugar Cane" brand hams, 1s. 2d.; local hams, 1s. to 1s. 1d.; cooked, 1s. 3d.; "Sugar Cane" brand lard, in packets, 11d.; in bulk, 10d. per lb.; local prints, 9d. per lb.

**LIVE POULTRY.**—The demand for live poultry has kept up well throughout the month, and supplies marketed, although fairly extensive, have met with ready clearances. The majority of the birds being marketed are only of the lighter breeds, and the small numbers of turkeys sent in have been poor to medium in condition only. Prime roosters, 4s. to 5s. 3d.; nice conditioned cockerels, 3s. to 3s. 9d.; fair conditioned cockerels, 2s. to 2s. 11d.; chickens, lower; heavy weight hens, 3s. 4d. to 4s. 3d.; medium hens, 2s. 4d. to 3s. 3d.; light hens, 1s. 8d. to 2s. 3d.; couple of pens of weedy sorts, lower; geese, 3s. 6d. to 5s.; prime young Muscovy drakes, 3s. 6d. to 4s. 6d.; ducks, good conditioned, 2s. 6d. to 3s. 4d.; ducks, fair condition, 1s. 6d. to 2s. 3d.; ducklings, lower; turkeys, good to prime condition, 11d. to 1s. 3d. per lb. live weight; turkeys, fair condition, 8d. to 10d. per lb. live weight; turkeys, fattening sorts, lower; pigeons, 5d. each.

**POTATOES.**—New local potatoes, 5s. 6d. to 6s. per cwt.

**ONIONS.**—New white or brown, 6s. to 7s. 6d. per cwt.

† Held over.

• In recess.

## AGRICULTURAL BUREAU OF SOUTH AUSTRALIA.

Every producer should be a member of the Agricultural Bureau. A postcard to the Department of Agriculture will bring information as to the name and address of the Secretary of the nearest Branch.

If the nearest Branch is too far from the reader's home, the opportunity occurs to form a new one. Write to the Department for fuller particulars concerning the work of this institution.

### REPORTS OF BUREAU MEETINGS. WOMEN'S BRANCHES.

#### THE USES OF HESSIAN IN THE HOME.

[By Miss ELLIE CAMPBELL, Inspector Domestic Arts, Education Department.]

*[Paper and demonstration given at the Lyndoch Conference, February 26th, 1931.]*

How often does mother say: "Oh, I wish I had a handy bag in which to put all these small parcels and packages," whilst she is shopping, especially when all the shops are far away and the necessary week's buying has to be done in one day. With a good bag, one that has been sent as a Christmas or birthday gift, made from either leather or a pretty tapestry, we are careful how it gets treated—no putting it on the floor, nor packing it till the sides appear to object. Instead of this extra worry and precaution, make a handy shopping bag from hessian.

Hessian is made from hemp or jute, thus it is a vegetable fibre, and can be treated in a similar manner to other materials of vegetable origin, such as cottons and cambrics, the only difference that the fibres are coarser and thus need a stronger dye.

If it is the shopping bag to be made, it will appear so much nicer if the hessian is dyed first, then worked up to the required style. It is easy to dye the material, but care should be taken to select a length of cloth that has the threads as even as possible and very few flaws, if any—that is, thick uneven threads. Run a line of large machine stitching around the edge to prevent fraying whilst it is wet. Soak the hessian in cold water until all the threads are thoroughly soft, as it takes some time for the dye liquid to completely penetrate each thread. Have a liberal quantity of strong dye—the same as a strong blue water on washing days—it takes a lot of dye to make a very satisfactory article. Put the wet hessian into the dye and boil it hard for about 30 minutes, wring it, and when hanging it out to dry be sure it is not creased or doubled up, otherwise it will not dry evenly. To obtain a good appearance it requires a lot of heavy pressing with the hessian very damp. When successfully done there is not much difference between dyed hessian and Arras cloth, but there is a large difference in price. Once the hessian is dyed and pressed it is simply a matter of designing the article and artistically working it up, and finishing it off. In this collection of useful articles various colored dyes have been used to show the effects, and also different materials—wool, raffia, linen, embroidery cottons—have been used to decorate the articles.

In these days of financial depression, when so many economies have to be made, it is generally mother who cuts out her own extra comforts so that father and the children shall not feel the pinch, but with very little expense—only a few pence—

several attractive devices can be made from hessian that will add comfort and pleasure to mother's work and to the home, perhaps there may be one or two articles that father can use.

For the shopping bag it will need a large striking design to work in nicely, as the threads are large and they do not allow fine stitchery to be successfully done. Work the design either in colored wool or raffia, line it with sateen or cretonne, then

sew it into shape and mount it on handles Here is one bag dyed a dark brown, worked with wools, and it has broad wooden handles that were made from the backs of two chairs that had been broken and were beyond repair. Another bag, a lighter brown

dye, worked with raffia, and supports let into hems at the top of bag with material handles sewn on. To make the bag more commodious, let a piece 2in. wide in each side. It will be found that the bag is comparatively light and very durable—it can be pressed often and the fresh appearance retained.

Think for a moment or two of all the walking and standing that has to take place during the day's work in the house, and, oh, how the legs do ache; well, with a little effort a handy stool can be made so that mother can sit down to do a number of tasks. Persuade father to make the framework for the stool, and then dye a strip of hessian, use colored wools and put rows of running stitch close together, to give the appearance of striped canvas, work eyelets in the hems so that it can be laced around the bars, and the result is this charming stool which can be easily folded and carried to any place where a task has to be done, such as cleaning silver, preparing beans, and numerous other duties. Similarly hessian can be used for a garden chair; for demonstration purposes this stool has an adjustable back, but the chairs are easily made with a rigid back. It is necessary to have strong hems that will not give away when a little strain is put upon them—double the hessian and be sure of the stitching. Work the strips for the back of chair to match the seat. By lacing the hessian on to the chair, instead of tacking it to the bars, it can be moved around and the wear does not come on the same line of threads all the time.

So far brown dyes have been used, but a very pleasing effect can be procured with lighter dyes. An old saying insists that flies—those opponents to hygiene and terrible pests to the housewife—do not like the color blue, so dye the hessian blue and ornament it with bands of floral cretonne, make a beading at the top and pass a rod through it, use as a curtain at the door. It will allow the air to pass in; will stand any amount of pulling as each person passes through; is sufficiently thick to keep the glare of the sun out, and yet will let plenty of light into the room.

If there is a bed on the verandah or sleepout, have a piece of dyed hessian with a beading top and bottom, ease it on to either a rod or cord and fasten to the top rail of bedstead and to each leg near the floor—this will always look tidy and will appear like a screen, taking away the appearance of a bed. One of the tasks of the housekeeper is to watch that the ticking of the mattress is kept in repair—of course, no one tears the ticking, it is worn by the rubbing on the wire mattress—so to guard against this wear put a covering of hessian over the wire and fasten it down along the sides and at the corners, this will give double life to the ticking, also protect the wire, and if the bed is used in a sleepout it will save the ticking becoming rusted from the wire, as any dampness in the air will cause rust to form. Make good hems, use tapes at the corners, and with tape sew the edge of hessian along the wire—this prevents the hessian moving whilst the bed is being made each day. Another use hessian can be put to in the sleepout is a bedside mat. Dye the hessian according to the color scheme desired; use the hessian double, to give weight and to keep the mat flat; stitch a hem 1in. or 2in. wide all around to save it curling up; work an attractive design on it.

For kitchen use there are many ways hessian can be used. With a double piece 12in. square, bind the edges with a colored bias bind to match the kitchen scheme, and put a tag at one corner with which to hang the cloth near the oven, and every time a hot saucepan or dish has to be lifted—there is the cloth, thick enough to prevent burning the fingers, and yet easily washed on washing day. A similar mat, but no bias binding, simply stitched around, used as a stand for hot saucepans and to protect the table; there is no harm when hot saucepans or baking dishes are placed on it instead of on the table. A little soda in the wash will help to take any grease out of the mat, whereas it takes time and plenty of energy to remove greasy marks from the table.

How often there is the tedious task of separating the scraps from the waste liquid? A handy and cheap rubbish strainer will solve the difficulty. Take a circular piece about 8in. in diameter and a straight strip for the sides—it can be made any depth

desired. Sew this strip to the circle, making a firm seam, this will form a round bag, put a hem around the top and run a piece of strong wire through it—forming a hook

one side and a long handle the other side. Now rest this over a petrol tin and pour all scraps and rubbish through the strainer. It is a fact that dry rubbish does not give off any unpleasant smell, nor does it attract flies to the same extent as it does

when it is wet; so if all scraps are put through the strainer the water can be used on the garden plot and the scraps dried, put in the burner or wrapped in paper and put under the copper on washing day, when the strainer could be scalded.

Then there are the "duster bag," "newspaper or magazine bag," "string bag"—all so easily made and very durable. The hessian can be used either plain or dyed to lend a little color to mother's kitchen—each one can have a place of its own; and oh, the hours of hunting and the questions that mother will be saved, for everybody will know just where to find the article he wants.

For washing days there is the peg bag, in which to keep the supply of pegs in the laundry, also the peg apron in which a few pegs are carried when pegging out the clothes. Some folk like a washing apron made of hessian, but when hessian is wet it is much heavier, and a weight like that hanging from the shoulders or neck is very tiring, and makes one weary. How often on washing day, whilst there is plenty of hot soapy water, most of the floor scrubbing is done? Now to protect the knees and clothing make a kneeling pad—two semicircular pieces of hessian 18in. along the edge, joined to form a cushion and stuffed with old material, about 2in. thick, keeping the stuffing smooth, then a double strip the length of curved edge and about 1in. thick—join the pieces together and put a tag on to hang it up when not in use.

Whilst mother is working baby cannot be expected to sleep the whole day, nor is it safe and convenient to have baby crawling about, and they love movement, so make baby a swing—one out of which he cannot fall. Take a circular piece of hessian about 15in. across (it depends on size of baby) and a piece of flannelette the same size, stitch them together all round, make a hem about 1in. deep in which to put a thick piece of window cord, or a piece of wire to make a firm edge and keep the swing open. Allow the flannelette to be the inside, as it will not irritate the tender skin. Cut two holes, each 2in. to 2½in. in diameter and about 4in. apart, and from 8in. to 9in. from the top—this is to allow the little legs to protrude and thus hold baby in the swing. Baby cannot get a firm enough hold to raise himself and overbalance. At equal distances around the top fasten four pieces of strong cord, and fasten these together about 2ft. above baby. This swing can now be hung under the verandah, or on a tree near where mother is working, and baby is safe and can enjoy its toys.

By this time it is clear that hessian can be a cheap article to use whilst working about the home—and one that will stand hard wear, yet can be easily handled. But a time comes for rest and pleasure, here again we can use the good old hessian. The feet are weary—well rest them on the small hassock which can be kept near the easy chair on the verandah, for the weather will not hurt it; and on the lounge have a brightly dyed hessian cushion, it can be elaborately worked with a cross stitch design, done in colored wools or worked in raffia. It is so serviceable and will stand any amount of throwing about by the children.

For the fire-side cushion, or humpy, hessian is a splendid material; it can be either dyed and worked, or used in its natural state and another cover of cretonne, shadow tissue, or tapestry put over it. They are such comfy seats by the fire of a cold winter night, when you want to get close in, and yet do not want to destroy the polish and surface of the legs of the chairs.

When father is driving home after a heavy day's work, he is tired, and oh, what pleasure to get into the car and rest against a soft cushion—one that just fits into the back and gives a sense of rest. It does not matter about having dusty clothes on, for it is only dyed hessian treated with colored wool, which was left over from some knitting. Shape the cushion like a wedge, so that it will fit into the back nicely. Have a strip of hessian about 15in. by 30in., and another piece 3in. by 45in. This narrow strip is to be shaped at both ends—cut off a triangular piece 1in by 15in. on either side of each end, and stitch this shaped band to the other piece that has been doubled—this will give a shaped cushion 15in. square, very narrow at one end and 3in. wide at the other end. It makes a good, strong wearing cushion at little expense.

After tea father removes the fire screen, which has been made from hessian, dyed a dark brown, and a suitable design worked with colored wools, and mounted on a hinged frame, the wrong side finished with a braid of same color as hessian; he puts a kindling to the fire and mother joins him, but she brings along her work stand, for lo, there are some socks and stockings that need a little attention, or perhaps some fancywork. This work bag is made of hessian, with applique on the outside to make it attractive. It is lined with a suitable piece of material, and pockets, in which to keep cottons, scissors, pins, and needles, are worked into the bag. A square of hessian dyed a green color and colored linen fruit applied on to it makes such a nice table cover for the verandah.

These articles, and many more, can all be made quite easily and with very little cost. Just remember to soften the fibres before putting material into the dye, and to have the dye of a good strength, then press the hessian whilst it is very damp. A bold design with harmonising colors will greatly enhance the appearance of the work.

### KEY TO FIGURES.

1. *Baby's Swing*.—The hessian is undyed and lined with a soft material such as flannelette.
2. *Tablecloth*.—The hessian is dyed a dark-green, hem turned up, and corners mitred. Colored linens applied in one corner to represent a cluster of fruit and leaves.
3. *Work Stand*.—The hessian is dyed a dark-brown; two semi-circular pieces for the sides, and a straight piece joined to the curved edges of the sides; line the bag with a pretty cretonne. The sides are gathered by means of draw cords, which are fastened to the cross pieces of stand.
4. *Work Stool (or with back, a Garden Chair)*.—The hessian is dyed a dark-brown, and strands of green and orange wools are run in rows to form colored bands in the hessian. Strong hems are necessary.
5. *Lounge Cushion*.—The hessian is dyed an orange color, and an original cross stitch design worked in colored wools—black, orange, and blue wools.
6. *Fire Screen (or on small scale a Telephone Screen for Table)*.—The hessian is dyed a medium brown, a band of green and yellow wools run across the top, and a simple design worked in wools at the bottom.
7. *Pouf (or Humpy Cushion)*.—The hessian is dyed brown. Two circular pieces, one for top and one for bottom joined to a longer piece which is sewn up the side. A cord is tied tightly around the middle of cushion.
8. *Small Cushion*.—The hessian is dyed and a simple design worked in colored wools.
9. *Motor Cushion*.—The hessian is dyed a nigger brown, and worked with orange wools. Make the cushion a wedge shape.
10. *Hassock*.—The hessian is dyed a brown, and the design may be stencilled on to it.
11. *Bedside Mat*.—Dye the hessian, use it double, and have deep hems. The design may be worked in wools or stencilled.
12. *Rubbish Strainer*.—Be sure to have the seams secure, or it might pull away from the handle. It is 4½ in. to 6 in. deep.
13. *Shopping Bag*.—The hessian is dyed a light-brown, lined with cretonne, and worked with shades of raffia.
14. *String Bag*.—The hessian is dyed a medium green, the opening is buttonholed with green wool, and the word "String" is worked in chain stitch. Paper bag or duster bag may be made by similar method.
15. *Shopping Bag*.—The hessian is dyed a very dark brown, lined with sateen, and wooden handles used. The design is carried out in colored wools.
16. *Oven Cloth*.—Plain hessian used double, bound with bias binding, and a tag put at one corner.
17. *Door Curtain*.—Dye the hessian a medium blue, put a heading at one end for rod or cord. Use floral cretonne to trim the curtain.
18. *Screen Curtain*.—The hessian is dyed blue, and a heading put at both ends for the rod to pass through.
19. *Peg Apron*.—Plain hessian bound with coloured bias binding, and simple design work in wools.
20. *Matress Cover*.—Plain hessian with firm hems all round, and tapes at each corner to fasten to matress.
21. *Window Screen*.—Plain hessian tacked to a frame, the back neatened with braid.
22. *Iron Duster*.—Plain hessian used double. This may also be used for a saucypan mat on end of table, near the stove.

**BUTTER MAKING.**

[A paper read by Mrs. A. NOTTLE (*Wasleys*) at the Lyndoch Conference, February 26th, 1931.]

At the present time there is a decided movement throughout Australia to improve the standard of the butter industry. The Dairying Act is encouraging the farmer to aspire to better and cleaner milking facilities and surroundings. South Australia has not the green summer fodder which is natural to Victoria and parts of New South Wales, and is so essential a part of good-flavored butter. Still, with a little trouble and pride in her work, the South Australian farmer's wife—even in the drier areas—can do much to improve the quality and flavor of her principal dairy product. *Feed.*—In winter, when green food is plentiful, butter improves in appearance and flavor. When feed is sown specially for cows, I prefer mixed cereals, such as oats and barley. Barley alone imparts to the butter a strong flavor, which is not appreciated. When feeding dry, I prefer crushed oats and bran, damped in very dry weather. It is most essential that cows have access to plenty of clean drinking water. *Milking.*—Milking should be done some distance away from all objectionable odors, such as pigsties, &c., and the cow's udder and teats must be thoroughly cleaned. This applies also to the hands, which should be rinsed before milking each cow. I keep a cloth and bowl in the shed for this purpose. *Separating.*—Separator and milking vessels must be kept perfectly clean. Wash them twice a day in warm water to which has been added a little washing soda, then scald with boiling water and leave to drain. A sunbath fairly often will ensure sweet and wholesome utensils. Always run the cream into an enamel or crockery vessel. See that any enamel vessel that is used is not chipped, or the cream will be tainted. It is not advisable to have the cream too thick—it is impossible to properly stir cream that is very thick. I add 1 tablespoonful of salt to each bowl of cream before mixing and stir the can of cream a couple of times a day. Never run freshly separated cream on to cold cream of a previous separating; this tends to raise the temperature, and it is important for good butter making that cream be kept at the lowest temperature possible. Cool the cream off as soon as possible after leaving the separator. In very hot weather keep a damp cloth around the vessel containing the cream, which should be placed in a draught to hurry the cooling process. When sending cream to a factory, send often and fresh. *Butter.*—Cream assimilates strong odors and flavors very quickly, particularly from such products as onions, fruit, &c. Care must be taken that it does not come in contact with these things. For butter, I prefer cream a couple of days old. Care should be taken to scrape the sides of the churn and beaters before the cream reaches the butter stage, otherwise this partly churned cream will 'make the butter streaky. If not using a churn, use a wooden spoon previously scalded and a crockery bowl. It is a mistake to churn the butter after it reaches the crumbly stage. If left at this stage for a few minutes the buttermilk will work out more easily. Drain off all buttermilk and wash thoroughly twice, then add from ½oz. to ¾oz. of salt to each 1lb. of butter and wash again. Leave stand for a few hours for the salt to thoroughly permeate the butter before pounding. I take what I consider 1lb. of butter and work it well, using a cloth previously scalded to soak up all moisture. The best time to make butter is toward evening, then "pound" in the early hours of the morning. Put in papers and allow to stand a while in a cool place to firm before marketing.

**FANCY WORK.**

[A paper read by Miss G. GEORGE (*Wasleys*), at the Lyndoch Conference, February 26th, 1931.]

Fancy work is an art from which most of us derive a certain amount of pleasure. Even the little girl in the kindergarten is taught to do darning stitches, working them into simple designs on cheese cloth, and comes to look forward to the afternoon set aside for fancy work at school. The days have long passed when girls would put in months at crocheting and working bedspreads and tablecloths, as was the custom in the days of our grandmothers, and which now we would discard, as out of date, and unsuitable to modern furnishings. The colored linens now so fashionable can be bought at any drapers for a very few pence, stamped with such easily worked and effective designs, that most of us would find it tiresome to bother about anything more complicated. In any kind of work, much depends on the choice of materials and threads, also scissors, needles, bodkins, &c., need a certain amount of care in selection. Scissors should be

sharp, and have fine points, or jagged edges will result, which are much harder to keep neat when working, and thus greatly spoil the effect of an otherwise good piece of work. Fine needles and thread usually produce the best results, and stranded cotton seems to be favored by most people, although D.M.C. is now much used, and is equally as good, and has a more lasting sheen. Many of us at some time or other have had a favorite design, which we have found very hard to match. This can be rectified by a little carbon paper, or, failing that, mix a little sugar and blue, and go over the lines of the faded transfer, allow to dry thoroughly, and then press with a hot iron in the usual way. I now wish to draw your attention to the ever-popular Richelieu work. It certainly takes longer to do, and requires more care in cutting out than most work; but, after all, do not the results more than repay one for the time spent in doing it? Then there is the seldom heard of Hedebo work. Like most needlework of real merit, it is of ancient origin, and has been introduced into this country from Denmark. Hedebo work consists of a number of simple shapes, such as circles, squares, lozenges, shields, &c., arranged to form a pleasing design upon the material, also a number of other stitches, such as satin stitch, snail train, or in fact any Mount Mellick stitches are employed, as these serve to throw up the pattern and increase the effect. Needles for this should not be too fine, a fine needle makes the stitches too close and firm. Thread used must be linen and of a fine and unfraying make. Knox's linen thread, No. 60, is recommended for the purpose. Stamped designs for Hedebo needlework cannot be obtained in Adelaide, so anyone taking up this work will find it necessary to buy the linen and draw their own. Care must be taken when choosing material to get it close and firm in texture; a soft, open linen is quite unsuited for this purpose. Any woman who decides to take up this work will find it most fascinating, and that the first piece will not be the last by a very long way. Last of all, there is tatting, which is very pretty in d'oyleys, &c., and makes a dainty finish when used as edgings for guest towels, handkerchiefs, fuji sets, children's frocks, and many other articles of wearing apparel. For making tatting, a small shuttle, not more than 2½ in. long, is best for all threads, excepting the very coarse. In winding thread around the shuttle, care must be taken not to wind too much at one time; this will cause the shuttle to gape apart at the ends. The thread mostly used is the ordinary mercerised crochet cotton, but for silk articles it is, of course, necessary to use Fibrone or any of the other numerous makes of reel silk. There is now so much machine work, which closely resembles the hand, and it is so inexpensive, that most people these days do not bother to interest themselves in hand work, which, it will be found, wears better, looks nicer, and for gift and other purposes is always much more appreciated.

### FRUIT DRYING.

[A paper read by MISS L. DENNISON at the Lyndoch Conference, February 26th, 1931.]

Of all the duties included in the term "household management" none demands such resourcefulness on the part of the housewife as the preparation of foodstuffs. The housewife who wishes to keep healthy those dependent upon her for good wholesome diet, should insist upon the daily consumption of fruit or green vegetables. In winter and early spring, this is rather a serious problem; on the whole, vegetables are fairly reasonable in price, but these do not take the place of fruit. A good supply of dried fruit

**WE ARE BUYERS AT HIGHEST MARKET PRICES**

on hand can be used to advantage to bridge the gap between the end of the apple season and the arrival of the stone fruit. Of course, they cannot take the place of fresh fruit, but they can be used very successfully. Drying is a primitive method of preserving food. In this operation a large proportion of water is extracted. As the apples are ripening, there are always a lot of windfalls with quite good apples going to waste under the trees. One method of partly eliminating this waste should be to dry the surplus apples. One of the most popular of dried fruits is the apricot. The apricot to be dried is not picked until it is fully ripened upon the tree; the riper the fruit the more sugar it contains, and the flavor becomes more fully developed. To keep apples and apricots a good color during the drying process, the fruit is treated with sulphur fumes. These are in such a diffused form that they are not at all injurious to health. Dried apricots make an ideal jam; 1lb. dried apricots equals the weight of 5lbs. of fresh fruit. *Dried Apricot Jam.*—Wash 2lbs. of dried apricots, soak overnight in 2 quarts of cold water, drain the water off into preserving pan and add to it 5lbs. of sugar, bring to the boil, add fruit, and cook quickly for half an hour, stirring constantly. *Apricot Conserve.*—3lbs. of dried apricots, one 2lb. tin of sliced pineapple, 6 cups of sugar, ¼lb. of almonds, 1 lemon. Wash apricots, soak overnight in 9 cups of water, cut pineapple and add with juice to apricots, simmer gently until tender, stir frequently, add sugar, boil 10 minutes, add lemon juice and almonds cut into strips, boil 5 minutes longer. An important advantage in using dried fruits is that jam made from them does not ferment. Again, the housewife may spread the jam making over a longer period of the year, and may cook these fruits, at least, when the weather is cool. Peaches, prunes, and duchess pears can also be dried successfully. There are many varieties of dried grapes. Raisins have been called the traveller's friend, for they are very nutritious.

### GELATINE.

[A paper presented by MRS. S. SCHUNKE (Wirrilla) at the Lyndoch Conference, February 26th, 1931.]

As quite a number of cold dishes contain gelatine, it will be well to learn of its different uses. The addition of gelatine to milk and milk mixtures prevents the formation of tough curds and enables the body to obtain the full amount of nourishment. The addition of a very small quantity of gelatine to baby's food ensures complete digestion. Medical authorities recommend the giving of 2 teaspoonfuls of this mixture just before each feeding period:—1 saltspoonful gelatine, ½ cup (½ pint) boiling water. For children 9 to 12 months old, allow ½ teaspoonful of gelatine to every pint of milk in the day's supply. Left over foods of all descriptions, such as meat, vegetables, fruit, and cake can be used and made into the tastiest of dishes by adding gelatine, and the housewife will find it invaluable, in that these dishes can be prepared any time and set aside until required. Fruit juices can be used for cake fillings, allowing one dessertspoon of gelatine dissolved in a little hot water, then stirred into one cup of juice, then set in a cake tin to fit the cake. When set, turn out and place between the layers of cake. Either lemon juice or a pinch of citric acid brings out the full flavor of the ingredients. Gelatine has no flavor, so add flavorings very carefully. A good plan is to taste the dish as it is flavored. Fruit should be stewed and flavored, the juice strained off, and measured by the cupful or half-pint, and if necessary water may be added to make the measure level. Always allow one dessertspoonful of gelatine to every half-pint of liquid, dissolve thoroughly in a little of the hot liquid, then add to the remainder of the fruit juice and mix well together, set aside and when beginning to thicken, add the fruit. When making a larger mould, care must be taken to see that the first layer is set before pouring in the next—if several colored jellies or fruits are used—to have three or four layers when turned out. Spices and curry for flavoring meat dishes are best sprinkled very lightly among the slices as they are being placed in the mould. Food is judged by flavor; no matter how good food is, if its taste is not pleasant, it will never be acceptable. A clear, well-flavored jelly is best for setting salads or vegetables; tiny individual moulds or eggcups are found the most effective to set these in. Salads served in this way, are very attractive. Beetroot in jelly preserves all the delicate flavor of the vegetable, and none of its juice is lost, for it surrounds the slices and cubes in the form of a jelly. Gelatine is used in a great variety of home-made sweets. It is useful as a thickening for soup and gravy. It is nourishing and enriches these liquids. It is also an excellent substitute for the whites of eggs in cake mixture. Eggs are often scarce, however, the cake still preserves its feathery texture by the addition of a dessertspoon of gelatine dissolved in a little hot water, then whipped to a stiff froth and beaten lightly into the mixture.

*Recipes.*—*Sheep's Tongue Shapes:* 2 dessertspoonfuls gelatine, 3 sheep's tongues, pepper, and salt, 2 cups stock. Boil tongues until tender, skin and slice finely. Arrange nicely in round cake tin. Fill tin with slices, then dissolve gelatine in clear hot stock, add pepper and salt, pour over tongues, and allow to set. Turn out and garnish with shredded lettuce, sliced tomato, and parsley. *Fruit Filling:* 1 dessertspoon gelatine,  $\frac{1}{2}$  cup hot water, 2 dessertspoons sugar, slices of fruit, peaches or bananas, lemon essence. Dissolve gelatine and sugar in hot water and add flavoring. Pour into a sandwich tin and arrange slices of fruit. When set, carefully turn out on to a layer of cake and cover. Cream may be first spread over. *Carrington Mould:*  $3\frac{1}{2}$  dessertspoons gelatine, small tin peaches, 4 dessertspoons sugar, 2 cups (1 pint) water, juice of a lemon, 1 cup milk, vanilla, cochineal. *Directions.*—For first layer: Strain juice from peaches, add water, lemon juice 3 dessertspoons, and  $2\frac{1}{2}$  dessertspoons gelatine. Place all in a saucepan on the fire, stir until gelatine is dissolved, pour a little into a round cake tin, and arrange thinly sliced peaches, pour in a little more jelly, then allow to set. The jelly left over will be required for the third layer. For second layer: Add sugar and essence to the milk and stir until the sugar is dissolved. Dissolve 1 dessertspoon of gelatine in a little hot water and when nearly cool mix into the cold milk and pour on to the peach layer. For third layer: Take remaining jelly from No. 1 and remelt if it has set, add a little cochineal, and when blanc mange is firm, pour on the red jelly and allow to set. Turn out on a flat glass dish.

#### WASLEYS.

December 4th.—Present: 28 members and five visitors.

Sister Machiel, of Gawler, spoke on "Nursing and her Experiences at Oodnadatta while Serving on the Inland Mission." Questions submitted through the Question Box were:—"What causes a sponge to fall after being taken from the oven?" Answer—Oven too hot. "What will take transfer lines that are not covered out of linen?" Answer—Glycerine. "Should tomatoes be watered in a trench or sprinkled?" Answer—"Through a trench mainly, but sprinkled occasionally to keep the foliage clear of insects." (Secretary, Mrs. A. Wilson.)

### SOUTH-EAST DISTRICT.

#### ALLANDALE EAST.

Meeting held September 5th. Present: 11 members. The meeting was devoted to consideration of the Congress agenda and Crop and Pasture Competitions. (Secretary, Mr. T. Earl.)

#### KONGORONG.

Ten members were present at a meeting on September 8th. Mr. A. S. Dixon read a paper dealing with "Luug Worms in Sheep," and a good discussion took place.

A further meeting was held on October 8th. Nine members were present.

DAIRYING ON SMALL FARMS was the subject of the following paper read by Mr. W. H. Downes (District Dairy Instructor):—At the present time, in view of the general financial depression existing in Australia, and as a direct consequence the low prices received for most classes of primary products, it would appear advisable for farmers to seriously consider turning their attention to something more remunerative and offering more reward for their labor. Dairying as an alternative has been suggested by those in a position to know in those districts which are suitable, as it appears to be the one industry which has been least affected by decreases in market values. During past seasons the Paterson scheme has in a large measure been responsible for the general stability of this industry, and the good prices received in Australia for dairy produce can be directly attributed to its operation. Without it, dairying generally would have assumed a much less healthy aspect, for instead of the supplier receiving 1s. 8d. to 1s. 10d. per lb. for butterfat, he would have had to be content with 1s. 1d. to 1s. 3d. per lb., or in other words, London parity price. Be that as it may, dairying still offers fair opportunities to the man so inclined to take it up seriously, and certainly appears to be the most favorable avenue to assist many South-Eastern farmers in making good on the land. I could quote numerous instances where the keeping of cows has proved the salvation or mainstay of hosts of farmers, who had they relied solely on other farming pursuits for their livelihood, would have assuredly gone under. Although there are some disadvantages connected with dairying, due to its being an all-weather occupation, necessitating constant attention, and possibly early and late hours, there are several redeeming features that should not be overlooked, and possibly outweigh any of the so-called hardships it involves. These could be briefly enumerated as follows:—(1) It

provides a regular and constant income, which may be the means of financing farm operations, &c., until such time as the main cheque is available; (2) the busiest time of its operation can be regulated so as to interfere as little as possible with other farming practices; (3) it provides a ready means of utilising on the farm fodders that might otherwise be considered useless or of little commercial value; (4) the by-products, such as skim milk, are available for the purpose of rearing young stock, such as calves and pigs; (5) the manure when conserved and applied to the land is most beneficial in maintaining soil fertility. *Advantages Gained by Enlarging the Herd.*—Many farmers who at present keep only a few cows would be well advised to increase their stock to the largest number possible to be kept with convenience. Usually the keeping of a few cows means that only a small quantity of cream is available, and, in consequence, delay in the delivery to the factory. In some cases the cream may be kept so long as to seriously affect its quality, and being of low grade, the supplier has to be content with correspondingly low prices. By having a larger herd, the supplier should almost invariably secure top prices, because having more cream to deliver, it will be sent more frequently, and in this way be much improved in quality. Apart from a quality point of view, there is no doubt that immediately a certain line of business is found to pay, and as a consequence is enlarged or further developed, it usually receives more care and attention to detail than was previously the case. *Profits from Dairying.*—Before discussing details and figures connected with the actual profits from dairy cows, it might be as well to mention certain essentials which may mean either success or failure. The intending dairyfarmer might well ask himself the question, In what way and by what improved methods can I hope to make a success of dairying? This very reasonable question can be answered as follows:—(1) By securing good stock in the first place, improving the quality and production of the existing animals, and culling out the poor producers; (2) by feeding consistently, intelligently, and economically; (3) by careful attention to the treatment and management of the herd; (4) by the proper care of dairy produce on the farm. Each of the foregoing suggestions will be dealt with in their order. (1) It is not intended to suggest that the farmer should invest in a pure bred herd. Such a procedure would entail a heavy outlay that would probably be beyond his means. He should, however, endeavor to secure a pure bred bull, with which his existing stock can be greatly improved until eventually the animals reach the standard of well bred grades. It is a well-known fact that milk or butterfat production is a hereditary characteristic, readily transferable to the young. Animals which have been bred from high producers, with this object always in view, should be almost invariably superior to those raised from common stock, with no special claims to breeding or production. Therefore, by introducing into the herd a pure bred bull, descended from a noted line of ancestors, a general improvement should be noticed in young stock, from both quality and production standpoints. This, generally, is the most economically method of herd improvement, particularly in this State, where a subsidy scheme for pure bred bulls exists. Under this scheme, any purchaser of a pure bred bull that is eligible is entitled to a refund of 60 per cent. of the purchase price. These bulls are of the right age for work (10 months to five years), and, besides carrying a health certificate to say they are free from tuberculosis, are the progeny of dams that have passed the butterfat standard for their age. This scheme, undoubtedly a generous one, should appeal to anyone who seriously contemplates improving their existing herd. Proper culling of stock by herdowners who are not members of a testing association will be a problem unless they decide to do their own testing. This should not be a difficult matter to the progressive man, and the small cost of the necessary equipment might easily be saved during the first year. Testing should be done regularly once monthly and full records of each cow's production kept for reference purposes. (2) The feeding of stock is equally important, as it is practically useless possessing good stock if they have not the wherewithal to produce abundantly. Although dry feeds, such as chaff and grain, will supply the bodily requirements of dairy stock, and in this way augment milk production, there is nothing to equal green fodder of the right kind. This need may be supplied in two ways. (a) By sowing down suitable pasture grasses and clovers which, when regularly top dressed, will yield an abundance of luxuriant fodder. Such growth will eventually choke out the valueless plants and weeds. It may be profitable to close up a section of the grazing area periodically for grass hay. This ranks high as a fodder for milch cows, and will prove very acceptable at times when there occurs a scarcity. (b) By supplementing the pastures with suitable crops which, if planted in rotation, will provide a regular supply of fodder. These may be either cut and carted out to the stock, or grazed, but the latter method, though involving less labor and time, is usually more wasteful. In districts where dairying is extensively carried on, it is generally the practice to sow more crops than are immediately required for feeding in the green state. The balance of these are usually placed in some form of silo and fed later on as ensilage. In crops so treated, almost the whole of the succulence is retained, and harsh or spiny plants, such

# SHELL PRODUCTS

Prepared in the adequately equipped Shell laboratories from unique resources, a special group of the highest quality products is available to the Australian Farmer.

If you require---

Better lubricated farm machinery;  
 Healthy trees and unblemished fruit;  
 Prevention of blowfly strike on stock wounds;  
 Freedom from flies, mosquitoes, moths, etc., in the home;  
 Quick and efficient means of temporarily marking stock;  
 Distinctive, fadeless and harmless sheep-branding;  
 Perfect lubrication to ensure longer tractor life;  
 Brighter lights and ideal heating for incubators and brooders;  
 The utmost power with economy from tractors;

The Shell Company Limited will gladly supply full particulars about the above products.

as thistles, are softened in the process and made palatable. There is a large range of fodders suitable as green feed for dairy cows. These include such crops as lucerne, maize, sorghum, Sudan grass, cereals, peas, and certain root crops. Lucerne, "the king of fodders," is one of the most useful if it can be grown in the district. It can be successfully grown without irrigation in districts with only a 20in. rainfall, and as a fodder crop has many points to recommend it:—(a) It is a profitable crop, and should considerably enhance the carrying capacity and land value of holdings. (b) Generally speaking, it excels most other crops in yield per acre and feeding value. (c) Its ability as a drought resister and soil enricher are well known. (d) It can be utilised in various ways—in its green state, either by cutting or grazing or converted into hay or silage. (e) The continual cutting of the crop helps to minimise the weed menace. (f) In comparison to its yield and fodder value, the cultivation and harvest costs are not excessive. (g) It is eminently suited to the feeding of all classes of farm stock, viz., cattle, horses, sheep, pigs, poultry. (h) The fire risks ever present in the case of ripe cereal crops, either standing or in stacks, are almost eliminated when lucerne is the chief forage crop grown on the farm. (i) Being a perennial, lucerne should not require replanting for a number of years, particularly if careful harvesting and cultivation methods have been employed. (3) *Treatment and Management of the Herd.*—The cow is an animal of regular habit, and responds favorably to such treatment. This means that the hours of milking should be as regular as possible, for there is probably nothing that reduces a cow's production more quickly than through being milked early one day and late the next. It is reasonable also to expect that cows will respond better when the milking hours are as equally placed as possible, i.e., as nearly approaching 12-hour intervals as convenient. Excitement, fright, or rushing about are not conducive to milk secretion; for this reason cows at all times should be carefully treated and dogs kept out of the cowyard. When cows are within three months of calving, they should be dried off and turned out to rest quietly in a suitable paddock away from the main herd. This should be large enough to permit of exercise and so situated that the animals are continually under observation. *Rearing the Calves.*—On small farms it may be inconvenient and hardly advisable to rear all the calves which are born. The farmer as far as he is capable will then have to select only the best calves for this purpose. Their healthy development will depend very largely on the treatment they receive and the feeding method employed. Newly-born calves, after removal from their mother, should receive the mother's milk (10lbs. daily) for the first week, or, failing this, as in the case of the death of the cow, add the white of an egg to each feed. During the second and third weeks whole milk will be sufficient, and the quantity increased to about 12lbs. daily. In the fourth week a gradual change may be made in the milk diet by breaking down the whole milk with increasing quantities of skim milk, so that by the end of this week the calf is on a ration consisting entirely of skim milk. It will now be necessary to replace the butterfat removed with a suitable substitute. Boiled linseed meal is recognised as being ideal for the purpose, added at the rate of half a pint of the porridge to each feed. Calves should receive milk ration till five or six months old; they can then be weaned and turned out to fend for themselves. In connection with calf feeding, it is most important to note that all milk should be fed at the correct temperature, i.e., blood heat, and be in sweet, fresh condition. Never vary from the regular quantity suddenly or appreciably, as calves allowed to overgorge will become victims of digestive troubles that may be infectious and frequently prove fatal. (4) *Care and Treatment of Dairy Produce.*—Although this item has been mentioned last, it does not signify that it is the least important. On the whole the climate of the South-East is very favorable in assisting the keeping qualities of cream, but unfortunately many suppliers place too much reliance in weather conditions, so that during warm spells cream quality often suffers, either through being held too long on the farm or some other form of neglect. The losses incurred through low quality cream may seem only slight, but if allowed to continue soon mount up, and might easily have been avoided if the cream had received reasonable care in the first place. The causes of low quality cream may be briefly enumerated as follows:—(1) Faults in the milking methods; (2) carelessness or neglect in connection with separating; (3) an unsuitable test for the existing conditions; (4) wrong treatment of cream after separating; (5) faults in the method of transport. Suggestions for correcting the above troubles are as follows:—Wash all cows' udders and teats prior to milking, and see that the milkers themselves are cleanly attired, with clean hands. The milking buckets, &c., should be kept scrupulously clean, and milk properly strained. The dairy buildings and surroundings should be well drained, clean, and free from objectionable smells. The separator should be taken apart after each skimming and the parts thoroughly cleaned and scalded. The butterfat test of cream should not be allowed to go to extremes, either too high or too low. For summer months, a test of 42 per cent. to 45 per cent. is recommended and for winter 38 per cent. to 40 per cent. Stir all cream regularly, and cool if possible during the summer months.

Stirring will tend to remove any gases developing in the cream and create an even ripening, whilst cooling will considerably retard any fermentation. Never mix warm and cold cream together, as the latent germ life in the latter will immediately assume activity under the more favorable conditions of temperature thus produced. All cream should be stored, in suitably tinned or enamelled containers, in a well ventilated room where the atmosphere is cool and pure. Transport is not always under the farmers' control, and in some cases difficulties or delay in transit may be responsible for inferior quality, as cream deteriorates rapidly when closed up for any length of time. Particularly is this the case in hot weather when cream may become exposed to direct heat while in the can. The supplier can at least see that the cream is forwarded as regularly as possible, and, if delivering it himself, should endeavor to keep the cans shaded from the sun. *Actual Returns from Dairy Cows.*—The average production of butterfat per cow in South Australia is estimated at 160lbs. per annum—a rather low figure. As there are a good many officially tested herds in the State that would practically double this figure, it naturally follows that there are also many remarkably poor producers. A conservative average for a good herd would be 240lbs. of butterfat per head. Estimating the value of butterfat all the year round at 1s. 6d. per lb., a cow should bring in approximately £18. In addition, there is the value of her calf and any surplus skim milk, but these items can be reasonably offset against the actual costs and working expenses of dairying. On high-class dairying land it might take two acres to run a cow, when the profit would be £9 or more per acre, but even on lesser land, if it took three acres per head, the return per acre would be £6. In conclusion, dairying should prove a profitable proposition in many parts of the South-East on suitable land, as the rainfall is generally fairly sure. Returns from dairying are regular and frequent, and there is possibly no other animal that returns more per acre in the closer settled districts of the world than the dairy cow. (Secretary, Mr. S. Johnson.)

#### KYBYBOLITE (Average annual rainfall, 22in.).

Fifteen members and four visitors attended the meeting held on August 15th, which took the form of a visit of inspection of the Kybybolite Experimental Farm. (Secretary, Mr. F. Martin.)

#### RENDELSHAM.

A report of the proceedings of the Annual Congress was given at the meeting held on October 4th by the delegates who represented the Branch at the various sessions. Twelve members and five visitors were present. (Secretary, Mr. F. White.)

#### TINTINARA (Average annual rainfall, 18.51in.).

September 27th.—Present: Eight members.

LUCERNE GROWING was the subject of a paper by Mr. D. O'Dea. Mr. O'Dea had grown lucerne for several years, and had 250 acres established on country of a sandy nature with a close subsoil and with water from 5ft. to 7ft. from the surface. The best method of sowing was to seed with a cover crop of oats or wheat, first sowing oats with 60lbs. of super and then cross sowing—without the discs of the drill—with 3lbs. of lucerne and another 30lbs. of super. The object was to sow as shallow as possible and yet cover the lucerne on a firm seed bed. It was very beneficial to spring-tooth the established plots, and if there was enough grass to carry a fire, burning improved the growth. Lucerne was most profitable when cut for hay and fed with oats or wheaten hay, thus making a balanced ration. As much as three tons per acre a year had been cut on his property. When feeding it was best to feed down quickly and hard, and to work the plots in rotation.

The Meeting on October 18th was held at the homestead of Messrs. McIvor Bros. It was attended by six members and five visitors, who made an inspection of the crops and pastures on the property.

The annual meeting was held on November 29th, 15 members being present. The annual report was read by the Hon. Secretary (Mr. B. Fotheringham), and officers were elected for the year.

### UPPER-NORTH DISTRICT.

#### (PETERBOROUGH AND NORTHWARD.)

#### APPILA-YARROWIE (Average annual rainfall, 14.69in.).

October 3rd.—Present: 14 members.

NEW HINTS FOR THE FARMER.—The Chairman tabled a coupling for horses. One end of the coupling had a spring clip made out of hoopiron; about 10in. of material was used, the clip being about 4in. long. On the clip was a link with a lip cut away, so that it would not cut the leather. The leather was adjustable to various lengths.

One member said that a blower for a forge could be made from a separator; another member said an old winnower also made a good blower. *How to Make Belt Dressing.*—Hold a tyre tube over a flame; every particle must drip. Do not allow pieces of tube to burn off and not melt. Allow the particles to drip into a pail of water. Later pour off water and bottle the melted tube and use as required. *Plough Grease.*—Melt tallow and mix with a little used crank case oil from a car and a little resin. The resin keeps the grease from running off the axle when warm. On no account allow the axle to become dry. *Brooder for Chickens from Incubator.*—Enclose a small space, leaving an opening for chicks to enter; cover space with a sheet of iron or as much as required, leaving enough room for chicks to get under iron. On the iron place stable manure, a fair quantity. Stable manure put on a dead beast and then set alight will entirely burn same, giving little smell, little smoke, and no flame. (Secretary, Mr. E. Wurst.)

#### MORCHARD (Average annual rainfall, 13.50in.).

September 12th.—Present: 15 members.

Mr. A. Piggott read the following paper entitled "Cows, Feed and Breed":—"In the keeping of dairy cows, feed is of more importance than breed. No other farm animal requires as much attention, so far as feeding is concerned, than the cow, producing as she does an enormous weight of milk during her lactation period. Consequently she must be well fed at all times to obtain the best results. In this district, cocky chaff could be used as a roughage, and with the addition of bran and crushed oats, makes reasonably good feed. Where mangers are not erected in front of the bails, the chaff should be fed out of nosebags to prevent waste. A stubble paddock should also be sown early with a mixture of oats and rye for green feed. Although feed is of such importance, it will be well to begin with as pure a strain as possible of the desired breed. If not pure-bred cows, at least a pure-bred bull should be used. The Dairy Cattle Improvement Act has done much to improve the class of cattle in this State, and more advantage should be taken of the subsidy in the purchase of pure-bred bulls, the bull being equal to 50 per cent. of the herd. Many farmers have the mistaken idea that pure-bred cattle are more delicate than mongrels. The mongrel, or scrub bull, as he is commonly called, is the dearest bull in the world, and the greatest menace to progressive and profitable dairy farming. The breed to be kept is a matter of choice, there being good milking strains in many breeds. If milk is required, the Friesian could be recommended; if for cream production alone, the Jersey would probably take pride of place. In a mixed farming district dual purpose cattle would be the better proposition, and for that purpose the Milking Shorthorn is hard to beat. There are good milking strains of them, they are exceptionally hardy, and are reasonably good for beef purposes. The calves sell well as vealers, or in normal seasons can be kept to fatten as steers. This State imports annually from other parts of the Commonwealth £200,000 to £400,000 worth of butter. The facts are that owing to the easier manner in which an income from cereals or wool was obtained and the less labor necessary, producers turned more attention to sheep and wheat growing, and in consequence dairying has languished for many years. In the year 1924 the number of cows in this State was 145,000, while in 1929 there were barely 100,000. The return from the herd is practically continuous throughout the year. When it is remembered that the cash returns from the factories are sent fortnightly to the producers and the money is thus quickly turned into circulation with immediate benefit to the State as a whole, the need for dairying is apparent. By experiments carried out in other parts of the world it has been found that growing children require at least one pint of milk per day. We seldom realise the benefit the cow is to us. Of all the animal friends of man, the cow is the greatest. If, as you are about to sit down to the midday meal, I might remove from your table what the cow has helped to place thereon, I would take the cup of milk waiting at baby's chair, the cream, cheese, butter, custard pie, cream biscuits, steak, roast of beef, and leave you to make a meal of potatoes, pickles, and pepper. There is not a thing from nose to tail that is not made use of by man. We use the cow's horns to make combs, her skin upon our feet, her hoofs make glue, her tail makes soup. She gives milk and cream, &c., and her flesh is the greatest meat of the nation. No other animal works for man both by day and by night. By day she gathers food and at night converts it into the things of which I speak." Messrs. Lillecrape, McCallum, Lang, and Tilbrook took part in the discussion which followed. (Secretary, Mr. A. McCallum.)

#### WEPOWIE (Average annual rainfall, 13in. to 14in.).

September 29th.—Present: 10 members.

In the course of a paper, "Care of Farm Machinery," Mr. J. Crocker said that few people realised the enormous sums spent annually by farmers in the purchase of machinery. The plant required for the working of an average wheat farm from

£500 to £750. The depreciation on machinery—frequently as high as 20 per cent.—was a very heavy charge upon production costs. The very high rate of depreciation was usually due to the careless use of implements, and costs of production could be reduced by bestowing a greater amount of care upon tools and implements. It was obvious that if machines were housed and kept in a better state of repair they would last much longer and do more efficient work. The saving of £25 in depreciation for one year was equivalent to a saving of 2d. per bushel in the production of 3,000 bush. of wheat. Three important points in the care of farm machinery were housing, repairing, and painting. A machine which was kept running when badly adjusted or when in a bad state of repair could not perform efficient service, and the rate of depreciation would be increased, because the wear and tear upon all parts of the implement was increased. Repairs should be made systematically and at times when there was no urgent productive work to be done. Nothing added so much to the appearance of a vehicle or an implement as a good coat of paint, though of greater importance than the appearance was the fact that paint was an excellent preservative. It filled the pores of woodwork, enabling it to resist the influences of air and moisture, and it protected metal from rust. A good discussion followed. Delegates to the Annual Congress gave a report of the proceedings of the Congress.

At a meeting on October 27th, which was attended by 10 members, Mr. J. F. Furns read a paper, "Possibilities of Reducing Costs of Production." He said it was difficult to see how costs of production could be reduced except by increased production per acre and more efficient farming practices. He stressed the importance of every farmer conducting some method of bookkeeping to enable him to find out which lines were paying best. To make the best use of their holdings they must go in for mixed farming. Sheep were a valuable asset. They cleaned up the fallow and weeds and fertilised the soil. A short discussion followed.

Meeting held November 25th. Present: Seven members. Mr. T. F. Orrock read a paper on the use of fodders, in which he said farmers in their portion of the State were, unfortunately, still experiencing an abnormal run of bad seasons, and would have to make the utmost use of limited fodder supplies. Every farmer should make provision to the best of his ability to conserve as much "cocky chaff" as possible. From experiences of last season, he found that all chaff and straw that went through a header was of considerable value. Stock preferred the rougher straw to the chaff. To get the most use from that rough type of feed it paid to damp it, and a little molasses would make it more palatable. The best method to make wheaten chaff go further was to add corn, and for that purpose he preferred pollard. However, as they had to consider also the cheapest method of feeding corn, crushed grain would be cheaper and almost as good. If it was not convenient to crush the grain, the best method was to thoroughly soften the grain by soaking it. It could then be used with the dampened chaff and would be less likely to cause sickness in stock. Barley could also be used in the same way. If it were well soaked that would lessen the danger of having it growing all over the fields. Most members had cut a little hay, and he thought it would be a good idea to include a small ration of hay occasionally—at regular times—to help keep the horses in better health. For conserving fodder when seasons returned to normal rainfall, he advocated, in addition to cutting a stack of hay, cutting a stack which could be headed for grain, and would provide a stack of valuable straw. Cocky chaff should also be saved. During the next year, or so soon as one could afford the time and labor, he advised making a pit for ensilage. A pit 66ft. x 21ft. x 6ft. deep would hold about 100 tons. The method had proved quite successful, and all realised the value even one such pit would be in times such as they were now experiencing. An excellent discussion followed. Mr. J. Burns did not believe in damping the feed, but preferred feeding dry and mixing whole wheat into the feed. When using cocky chaff or straw only, he added wheat at the rate of ½ bush. per feed for eight horses. His team did all the work on that ration and held their condition. He considered that it was by far the cheapest method of feeding a team. Mr. G. Gregurke always used a fair amount of molasses when feeding cocky chaff or straw to horses, mixing a little pollard with it in preference to wheat. Mr. J. Crocker preferred feeding either oats or bran with cocky chaff undamped. He considered that chaff carriers should never be taken off the harvesters even in years of plenty, because they served a twofold purpose, saving fodder and gathering weed seeds. Mr. L. Jasper favored the stripper instead of the harvester during lean years, because more cocky chaff was gathered and it was of a better quality than harvester or header chaff. For several years he had fed mostly straw and cocky chaff, and had found boiled wheat suitable for mixing with it, though it should not be fed sour. Mr. E. Roocke preferred feeding, where possible, hay chaff in conjunction with cocky chaff, mixing it with molasses diluted in water and adding either half each of bran and pollard, or else crushed wheat at the rate of one-third of a kerosene tin per feed for 12 horses. When feeding

on cocky chaff only, he used boiled wheat at the rate of one kerosene tin per 12 horses daily, chaff allowance being a wheat bag full per horse per day. If the chaff was of reasonable quality, the horse did well on that ration. (Secretary, Mr. E. Rocke.)

WILMINGTON (Average annual rainfall, 17.63in.).

On September 23rd Mr. C. Goddard, of the School of Mines, gave a wool classing demonstration in Mr. H. Hampel's shearing shed. In the evening Mr. Goddard spoke on the subject, "Sheep and Wool for the Farmer." Present: 27 members. (Secretary, Mr. H. Stevens, Terka.)

## MIDDLE-NORTH DISTRICT.

(PETERBOROUGH TO FARRELL'S FLAT.)

EVERARD EAST.

The monthly meeting was held on September 6th. There was an attendance of 13 members. A paper was read by Mr. A. Hentschke on cultivation of fallow and stubble land. In the discussion members were of the opinion that in their district fallow should only be harrowed after summer rains, and that nothing was gained by cultivating weed-free dry stubble before sowing.

At a further meeting held on October 8th there was an attendance of 10 members. Mr. C. Hughes gave a report of the Annual Congress. (Secretary, Mr. F. Hughes, Blyth.)

GLADSTONE (Average annual rainfall, 16.40in.).

At the meeting of the Branch held on September 19th Rev. Geddes White delivered an instructive address, illustrated with lantern slides, "The Nile of Australia." (Secretary, Mr. F. Chick.)

KOOLUNGA (Average annual rainfall, 15.52in.).

Mr. H. Spencer presided over an attendance of 12 members. An interesting report of the Annual Congress was given by Mr. G. Pedler. (Secretary, Mr. E. LePage.)

## MURRAYTOWN.

August 9th, 1930.—Present: 13 members.

**ECONOMY ON THE FARM.**—Mr. F. Borgas read the following paper:—"With the present low prices of farm products, the farmer has to practise economy wherever possible. *Farm Machinery.*—Where the ground is not too rough and hilly, large machines should be used. The work can be done in less time, wages are reduced, and there will be very little difference in the upkeep than of a smaller machine. On small holdings the farmer has to study economy in the way of conservation of fodder for stock, because he generally sows and reaps as much land as possible to be able to pay expenses and make a little profit. Most farmers only cut enough hay to see them through the year, and when drought years are experienced are short of hay before the end of the year. Every farmer should have a cocky chaff carrier on his machine when reaping. If one has a few good heaps of cocky chaff as a stand-by, it will save much worry and expense when feeding stock in dry periods. One or two good straw stacks should also be made. They are good feed and provide shelter for stock in winter. I do not favor tipping the cocky chaff in small heaps about the paddock when reaping. If the chaff is dropped at one corner of the piece or wherever the wheat heap is made, it can always be made into a large heap and the quantity spoilt in case of rain before carting is commenced will be reduced to a minimum. A well equipped blacksmith shop is also necessary. No matter how careful one may be, breakages occur, and if the farmer has a blacksmith shop he can do most repairs promptly and satisfactorily. In this way much expense and valuable time will be saved; but he should not undertake jobs that he is not capable of doing. The saddler's account can be reduced if a side of leather and a few copper rivets are kept on hand for repairing leather work. All leather harness should be oiled or greased at least once or twice a year. This will preserve the leather when it is exposed to the weather. Neatsfoot oil is a good leather softener, but is rather expensive. Crank case oil drained from cars or tractors has the desired effect and is not so expensive. Super bags should be thrown in a water hole soon after seeding, and allowed to soak for a few days. They should then be hung up to dry, when they can be used for oats, barley, and seed wheat. Old galvanized tanks should be cemented inside and outside, and they will still be of considerable service. A few sheep are also very profitable on the farm. They supply the house with mutton

and help to pay the bills with wool and skins. It will be more profitable if farmers keep a few good cows, instead of a herd of wasters. Pigs should also be kept in conjunction with dairying. Many farmers do not realise the full value of pigs, and it is surprising that such a few farmers keep pigs. They help to provide the house with ham, bacon, lard, and sausages, and convert second-grade wheat and other waste into profit. Most farmers make a practice of selling all the grain they produce, even when the price obtained for it is below production costs. It will be more profitable to dispose of some of the wheat in the form of fat pork. A few fowls can also be kept on the farm. They keep the house in eggs and help to reduce the store account. A circular saw and bench should also be kept handy to the engine; two men can then saw enough wood in half a day to keep the house going for 12 months. A saving can also be effected by devoting a small piece of land to a vegetable and fruit garden, providing sufficient water and time to attend to it are available. It is also necessary for those in charge of the domestic duties of the farm to study and exercise economy.

A further meeting was held on August 28th, when Mr. J. O. Hatter, District Dairy Instructor, gave an address, "Profitable Dairy Farming." (Secretary, Mr. E. Pitman.)

The Hon. Secretary, Mr. E. Pitman, gave a *resume* of the 41st Annual Congress at the meeting held on October 4th. Present: six members.

#### REDHILL (Average annual rainfall, 16.63in.).

At a meeting held on October 7th, attended by nine members, Mr. M. M. Coffey delivered an address, "Our Present Position as Primary Producers," and a discussion followed.

The meeting held on February 3rd was devoted to harvest reports. Each of the seven members present gave a report on his harvest. (Secretary, Mr. S. Pengilly.)

#### YANDIAH.

Eighteen members attended the meeting held on September 12th, when Mr. E. L. Orchard (District Agricultural Instructor) delivered an address, "Fodder Growing and Conservation." (Secretary, Mr. F. Jettner.)

### ALMA.

Meeting held September 9th. Present: 12 members. Mr. W. C. Johnston (District Agricultural Instructor) delivered an address, "Weeds and their Control." (Secretary, Mr. E. Drescher.)

The Annual Meeting was held on August 5th. The annual report was received and discussed. Present: nine members.

### BUCHANAN.

Fourteen members and two visitors attended the meeting held on October 3rd, when the Secretary, Mr. L. Bell (Marrabel) gave a report of the Annual Congress.

CLARE (Average annual rainfall, 24.61in.).

September 2nd.—Present: 23 members.

Short papers were read by junior high school members on the subjects: "Lucerne Growing," by E. O'Shaughnessy; "Summer Fodders," by L. Gilchrist; "Top Dressing," by T. Gill; and a milk testing demonstration by L. Walker and R. Smith. All were well received and freely discussed.

At a meeting held on October 7th, with an attendance of 21 members, Messrs. J. Scales and H. Hicks gave a short report of the Annual Congress. Mr. J. B. Harris (Horticultural Instructor) delivered an address, "The Codlin Moth." Many questions were answered by Mr. Harris, and a good discussion followed.

A further meeting was held on October 28th, with an attendance of 18 members. Messrs. C. Neate and P. H. Quirke gave papers on "Cincturing."

Mr. C. Neate in his paper stated that before "cincturing," or "ringing," as the operation was more commonly known, the growing of the Zante currant was not a payable proposition. The setting of the fruit was light and the bunches most irregular. The practice was introduced by the late Mr. W. G. Grashy, after his trip to Europe, and was carried out on the arms instead of on the trunk as at present. The object of "cincturing" was to cause the berries or grapes to set more evenly, and this was brought about by checking the flow of elaborated sap back to the roots. The best time to carry out the operation was when about 50 per cent. of the caps had fallen from the flowers; the best setting and sample he had noticed was on the vines cinctured last, and now he was going to commence even later, that is when more than 50 per cent. of the caps had fallen. He drew attention to the fact that last year the bees had forced a large percentage of the caps off and he had started on three rows, and then stopped. The three rows cinctured early had irregular bunches and a poor sample. The speaker stated that a large percentage of the vines were over-cinctured, and this was the cause of poor growth; in some cases where his vines had been attacked by black spot in the wound, he had not cinctured for three years. Last year he had left the vines on sandy ground, and the returns were heavier and the samples better. These points went to show that the vine had to be studied according to the growth it was making and the seasonal conditions. The implements or tools which might be used were confined to two types, that of a piece of hoopiron made into the form of a saw, and the double knife. It was recommended to only use the saw on vines, say, 15 years and over, while the knife was the more suitable for younger vines. A clean cut one-sixteenth inch in width was best. The operation must be conducted most carefully. Many of the patent ringers were more suitable for the gum trees than vines. On examination of the older vines it would be found that the wound had healed only three-quarters of the way, or was only living by a few strips—these had been let go, and after a few years had regained their strength. The cincturing should be kept as low as possible on the trunk to obtain as uniform a stem as possible; occasionally on a high trellis there was not enough foliage to shade the stem, and the bark in the sun did not heal, mostly on the west side. Under these conditions, the cincture could be made higher up. In conclusion, Mr. Neate stressed the facts that the operation should be carried out with great care, and one should not be in too great a hurry to commence the work. The following paper was given by Mr. P. H. Quirke:—"Cincturing": Among the varieties of grape vines there are two which differ in many respects from the others. These are the "Zante Currants" of commerce, and the "Sultana." Both varieties are seedless, and in much demand in their dried form. In order that payable returns may be obtained from vineyards planted with these vines, it has been found necessary to adopt artificial means of setting the fruit at the time of blossoming. The method used is referred to as "cincturing," or as it is more commonly called, "ringing." Cincturing consists of removing a strip of bark from the main stem of the vine. The strip of

bark removed varies in width according to the vigor of the vine, but usually does not exceed one-eighth of an inch, and in most districts is not nearly so severe. The variations are referred to as "heavy" and "light" cincturing. The ring of bark is taken out so as to completely encircle the main stem of the vine. Currant vines, and to a lesser degree, the Sultana, will throw off the majority of the berries on the vine unless the vine is cinctured, and the fruit from an uncinctured vine is usually small, and the bunch of fruit straggly in appearance. The time to cincture is when the flowers are from half to two-thirds open. There is a difference of opinion among growers as to the correct time, but careful testing has shown that it can be done too early and too late, and the half-way line undoubtedly gives the best results. The young vine should be cinctured for the first time on the oldest wood close to the ground. The reason for this can be clearly seen when it is remembered that the cincture heals downwards, and during the time that the sap is retained above the cincture, considerable expansion takes place in the stem of the vine, and cincturing for the first few years close to the ground gives the vine a sturdy stem to carry the weight of fruit. Do not cincture the young wood unless absolutely necessary, the reason being that until the vine is eight or nine years old there is very little of the hard wood core in the stem of the vine, and unless extreme care is exercised, irreparable damage can be done to the young vine. When the vine is about nine or ten years old, the cincture can be made in a more convenient position, but it is advisable to always cincture under last year's cut, commonly referred to as "ringing downwards." Opinion is divided on this question, but when the question of healing comes into consideration, and it is remembered that the sap is retained above the cut and heals downwards, it will be understood that a badly healed cincture of last year can be covered over by the expansion of the vine above the cut. When treating a badly healed cincture, always make the cut at least 3 in. under the old scar, because the bark under a bad cincture is very thin close to the scar, and the damage can easily be increased by tearing. The tools most commonly in use are the single knife, saw, and double knife, with numerous other more or less effective instruments, nearly all of which have been designed to speed up a tedious and very tiring practice. The single knife is used on the young vine for the first cincture, which consists of two single cuts about 1 in. apart. This practice, besides being almost entirely ineffective on vigorous young vines, can be positively murderous when done by careless hands. The slightest pressure forces the knife into the sapwood, and excessive "gumming" will be noticed, denoting a supreme effort on the part of the vine to repair the damage. Vines have been known to die off above the cut so great has been the damage. Another point against it is if the knife should be tilted when making the cut, it will lift the bark. It needs very little thought to arrive at the result of this damage. The saw is the cincturing medium used by the majority of growers in the Clare district, and I say here from observation and practice, that no more devastating tool has ever been used to gain growers a livelihood. I readily admit that there are many old vineyards where no other tool can do the same work in so short a time, but in too many instances vines are being sacrificed on the altar of speed. The saw cut is certainly effective in setting the crop, but it is doing more to cut short the lives of vineyards than all the diseases in the currant growers' calendar. If the saw is used to cincture the bark only, no great harm can result; but the damage is done by the heavy hand that restricts the ascending as well as the descending sap. "Heavier" and "light" cincturing is interpreted by the depth and not by the width of the cincture. The double knife, which takes out a strip of bark in one clean cut, is the tool which, in my opinion, does the most satisfactory work and compensates for the lack of speed. The double knife was in common use before misguided genius introduced the saw, the main qualification of which is speed, and in the best interests of the currant industry the saw should be relegated to the limbo of forgotten things, the exception being old vineyards that have knotty and gnarled vines, and even in these vineyards a single-bladed knife in conjunction with the double blade will do much to overcome the obstacles met with. A clean cut will always heal better than a ragged one, as is proved in tree pruning, when a larger cut is made with the saw. If the cut is smoothed around the bark with a sharp knife, the wound will heal over much more rapidly than the bruised surface left by the saw. The vine is a very hardy example of plant life, but abuse of the practice of cincturing will sap its vitality, and soon render it unproductive and profitless. In these times when quality counts, it is necessary to study the currant industry from every angle, and everything that will improve our product should be carefully considered, and I am confident that cincturing plays a big part. Without the cincturing, the currant vine is useless, and the practice made the industry possible, and is therefore all-important, and worthy of the greatest care in application. Many questions were asked and experiences related. Mr. E. H. Mattner spoke of the use he had made of topping where he had to cover large

areas, and was "running late." He had just taken off the tip of the shoots, not a large amount, with a knife, the topping had checked the vines enough to permit of the cincturing being carried out carefully, which he had found very essential. In some cases a second cincture had been carried out, but members suggested that the tipping or lightly topping the shoots would be worth while trying. Mr. L. Dux drew attention to the fact that many growers became too excited about cincturing, and as soon as the caps commenced to fall they were anxious to start. He said it was better to let all the caps fall than to worry about not being finished in time. He had found that he had the best results where the cincturing was carried out on the vines with the caps off.

Meeting held December 2nd. Present: 13 members. A short report of the Conference at Angaston was given by Mr. H. Lawrence. Mr. J. O. Hatter (District Dairy Instructor) delivered an address on dairying. (Secretary, Mr. H. Ninnies.)

## MIXED FARMING IN THE LOWER NORTH.

[A paper read by Mr. G. BUCKBY (Wasleys) at the Lyndoch Conference, February 26th.]

To conduct a mixed farm successfully, it is essential that all sections of the industry must be made to pay individually. The main items in our district are hay and wheat, and to get the best results from these crops, you must fallow the land as early as possible. June and July is the best time for winter fallow, and gives a far better chance of getting a good seed bed, especially in dry years. Fallow should always be worked well to keep weeds down and to prevent a crust from forming on the surface. It is very important that fallow should be worked after every rain, particularly after summer rains. When the fallow has been thoroughly prepared, select nothing but the choicest and purest of seed wheats, at the same time taking into consideration their suitability for the district. For best results, all oats or wheat should be sown not later than the month of May in the Wasleys district; later sowing nearly always shows a great reduction in yields, both for hay and wheat, and has done so for over 50 years. Multing or Cape barley sown in June usually yields well, and would be too rank sown earlier. With regard to sowing of superphosphate, I strongly advise farmers never to sow less than 1cwt. of super to the acre with any crop. When the crop is ready, cut for hay or reap for corn, whichever pays the better, according to prices and yields; but, nine times out of ten, hay pays better than wheat in the Wasleys district, if one sells on the right market. Barley is not always payable with regard to price, but is very valuable for crop rotation. It is a crop that can always be reaped and obviates the necessity for cutting large quantities of hay, as in the case of oats as a change crop. Oats are the most essential and efficient change crop for building up the soil for wheat growing in our district. If we sow wheat on the same land two years in succession, yields are definitely lower in the second wheat crop, and the difference in the crop can be seen right throughout the year. Indian Runner wheat is almost as good as an oat crop in its soil-building qualities, but it is a hay wheat and does not, on the average, yield satisfactorily as a corn crop.

*Dairying.*—The industry which holds second place on a mixed farm is dairying, combined with pig raising. The cow is a very profitable and productive animal if fed well and managed properly. A cow must have adequate shelter in winter from cold, bleak winds, or she will become unproductive, even with the best feeding. The cream produced is either made into butter or the cream sent to the factory, the by-product in the form of separator milk can greatly assist in the feeding of pigs and saves feeding so much corn to them, which usually is of greater value than separator milk. Milk is essential for sows with young pigs and they will not thrive satisfactorily without it. To cut down costs of pig raising, it is absolutely necessary that there should be small paddocks adjacent to the piggeries, these paddocks to be sown with Cape barley or lucerne. The green feed paddocks can be fed off in rotation and save a good deal of corn feeding. Green feed materially improves the health of the pig, as also does the exercise and freedom gained in the paddocks. Generally, the most profitable age at which to sell young pigs is from six to 10 weeks whenever possible. I do not favor the keeping of pigs to be large enough for bacon, unless the necessary foodstuffs are very cheap at the time and the marketable prices very low. The pig can be very cheaply reared if natural feed is plentiful. If every heifer calf is reared, a herd of young cows can be soon built up at very little cost, and the older animals can be profitably sold when the young cows come into profit. In any case, the cow is an absolute necessity on the farm, even if only kept for home requirements—fresh milk and butter.

**Sheep.**—Sheep are an excellent side line on a farm to utilise feed that would be otherwise wasted, and in the farm sheep one has far cheaper meat than buying it from the butcher, provided good judgment is exercised in buying and selling of the farm flock. The sheep is very similar to the cow in that its numbers can soon be doubled if success is achieved with lamb raising. Wool usually is a fair price, and is one of Australia's greatest wealth producing industries. The rearing of young horses will become a very lucrative branch of the farming industry, because there have not been so many young horses reared the last few years as previously, and tractors are wearing out and being replaced by horses in many parts of this State. These facts will tend to greatly increase the price of the good stamp of farm horse.

**Gardening.**—Gardening is a very profitable side line which should be carried on by everyone who has a house and a little land around it. Various kinds of fruit trees and vines should be planted for usefulness and to beautify the home. Nearly every kind of vegetable can be grown here, and can be planted in rows underneath the fruit trees. At least three crops a year can be grown on the same ground if heavily dressed with farmyard manure and properly worked to keep a rich, deep loam. Much money can be saved if a farmer grows all his own vegetables, and more vegetables can be used if grown in the home garden, because of the cheapness. The time required is very little to maintain a small home garden on a farm, and efforts in this direction will be amply repaid. A lawn and flower garden assist in beautifying the front of the home, and cost very little, but they improve the value of a home wonderfully.

**Poultry.**—Geese, fowls, turkeys, ducks, and pigeons are a very good assistance towards making mixed farming pay. All poultry sells well throughout the year, and especially during the festive seasons. The income from eggs greatly assists in making things pay, and for many months of the year poultry live on corn about the farm that would otherwise be wasted. Chicken raising can be carried on to advantage if managed properly. Lucerne is a very valuable food for poultry and is almost a necessity. I maintain that the farmer who carries on mixed farming thoroughly will be in a better position always than the man who just grows hay and wheat and perhaps keeps a few sheep. The mixed farmer can pay all his small debts throughout the year from his side line income, and in many cases has all his harvest money to bank at interest, provided he is not buying ridiculously expensive land.

#### FARRELL'S FLAT.

Meeting held September 26th. Present: 15 members. The Secretary, Mr. A. Brown, addressed the meeting on the subject, "The Value of the Department of Agriculture and the Agricultural Bureau."

#### LYNDOCH (Average annual rainfall, 23.58in.).

Meeting held October 7th. Present: 19 members. Matters of local interest were discussed.

At a meeting held on December 2nd, which was attended by 13 members, Mr. H. Kennedy gave a brief report of the proceedings of the Conference at Angaston.

Twenty-three members attended a meeting on January 6th, when matters in connection with the Lower North Conference were discussed.

A meeting held on February 3rd, with an attendance of 16 members was devoted to the same subject. (Secretary, Mr. J. Hammat, Williamstown.)

#### MODBURY.

Fourteen members attended the meeting held on September 12th, when Mr. A. Edquist, of the Education Department, gave a milk testing demonstration. (Secretary, Mr. M. Murphy.)

#### OWEN.

Meeting held September 29th. Present: 10 members. Delegates tendered reports of the Annual Congress and papers referring to the world's position of wheat and wheatgrowing were read and discussed. (Secretary, Mr. A. Bowyer.)

#### PENWORTHAM.

The meeting was held at Seven Hills and was attended by 22 members. Mr. J. B. Harris (District Horticultural Instructor) gave an address, "General Orchard Work." (Secretary, Mr. A. Jenner.)

#### RIVERTON (Average annual rainfall, 20.81in.).

Meeting held October 6th. Present: six members. The meeting took the form of a Question Box evening. Several subjects were brought forward, and an interesting discussion followed. (Secretary, Mr. O. Longbottom.)

## ROSEDALE.

Meeting held September 9th. Present: 11 members and two visitors. Mr. F. Waddy (Manager Turretfield Demonstration Farm) delivered an address, "Topics of the Day." (Secretary, Mr. H. Muegge, Sandy Creek.)

## SADDLEWORTH (Average annual rainfall, 19.65in.).

September 5th.—Present: 12 members and three visitors.

CONSERVATION OF TREES.—Reading a paper on this subject, Mr. G. Friebe said it was a matter for regret that with the large number of trees that were being cut down right through the country districts, very little was being done in the way of replanting. Those engaged in the bee-keeping industry had already drawn attention to the harm that was likely to be done to the export trade in honey as a result of the cutting down of trees. It was admitted that on arable land trees had to give way to the cultivation of cereal and other crops, but on rough, hilly country, trees were too often ringbarked solely for the purpose of growing grass. He urged farmers to give serious consideration to the planting of trees on their properties. They would provide a source of revenue for the beekeeper, give much needed shelter to stock in summer and winter, and furnish posts and firewood for the farm. Mr. L. J. Burton read a paper, "The Wife's Right to Pledge her Husband's Credit." (Secretary, Mr. A. Blundell.)

## TRURO (Average annual rainfall, 20.21in.)

September 8th.—Present: 14 members.

SHEEP AND WOOL.—Mr. W. Scott read the following paper:—"The most profitable sheep to be kept in this district is the Merino, and for the purpose of wool-growing alone this breed stands above all others, especially so in dry districts. This district is also very suitable for fat lamb raising, and should prove very profitable to farmers who keep 100 to 200 sheep. In raising fat lambs, a crossbred would be the most profitable. Quicker returns are secured by using a large-framed Merino ewe (three or four years old) with a Dorset Horn, Shropshire, or South Down ram. A point in fat lamb raising is to get the lambs to market in a nice fresh condition. Wool growing and fat lambs are the two industries which should prove the most profitable in this district. All the sheep should be of good constitution and entirely suited to the district. There are many things the sheepowner should try and avoid, perhaps the most important is overstocking, as no one can expect to get the most out of the sheep if they are half starved. It is far better to be on the safe side and always try and keep a little feed in the paddocks, then if a drought does come the sheep should be in good condition. Anyone knows that in bad times poor and half-starved sheep are not of much value. Dealing should also be avoided; a farmer loses far too much valuable time in attending markets when he starts dealing, and very often shows very little profit after wasting much time. It is a much better proposition to have a permanent flock than to be always buying and selling. The best time for lambs is about April-May, and that means joining the rams with the ewes in the middle of November. When joining the rams the ewes should be in good condition, but not too fat, and on very good feed if possible. The ram should be in strong, vigorous condition, but when using other than Merino it is very easy to have them too fat. Three rams should be joined with 100 ewes and left for six to eight weeks, and it is a good plan to yard them occasionally. About a month before lambing ewes should be crutched. If breeding crossbred lambs, the ewes need more attention at lambing time and should be watched closely, otherwise ewes as well as lambs may be lost. Young ewes have trouble in lambing to the bigger framed rams. Lambs should be tailed at about four to six weeks old. I have always used the searing iron, and consider it the better way; when the tails are cut off the lambs lose a considerable amount of blood, which checks their growth for a time. Instruments used in tailing and ear marking should be disinfected—a solution of 5 per cent. ordinary washing soda used hot is quite a good disinfectant. Shearing, where possible, should be done about the same time each year. A couple of weeks before shearing all sheep should be got in and all dirty and draggy ones crutched. Branding should always be done neatly, and the brand always put on the right place. A line of sheep well branded in a sale yard are much more attractive to a buyer. The correct time for dipping is about six weeks after shearing. Wool.—Good wool should show plenty of character, it should possess a good even crimp, and be well developed, which indicates good breeding. Condition also pays an important part in wool classing. This refers to the state of wool, whether it has grease or yolk in it. This wool is termed heavy condition, while wool with little or no grease is termed light condition. Wool classing at all times should be done honestly and carefully, the fleeces should be well skirted, very burry or dirty pieces should be taken off and fleeces generally should be skirted as evenly as possible,

and good judgment and care is essential. In classing the fleeces all the yellow, heavy-conditioned fleeces should be taken out and baled separately, also all very coarse and short stapled and tender fleeces should be taken out. With farmers, where it is only advisable to have two classes, all of these just mentioned could be baled together, and where there are enough sheep, all of the ewes' hoggets', and wethers' fleeces should be baled and branded separately. If possible make the lots in four or more bales. Lots of under four bales—"star lots"—do not receive the same amount of competition as do the bigger lots. Pieces should also be in two sorts—first pieces and second pieces. The first consists of all the bigger and cleaner wool, and the second of trimmings and dirty edges of the bigger pieces. Stained wool should be kept out and packed in a bag, and pizzle pieces should always be taken out of the wethers' bellies. Bellies also have to be baled separately. Floor and table locks are baled together. Very sandy locks should always be taken out. All first fleeces should consist of all the bright, light, and most attractive fleeces, while the seconds are made up of all yellow, short, and tender fleeces, and in bigger clips another class should be made of all the stronger quality fleeces which may be very light, but it does not pay to put very strong, coarse wool in with the best fleeces when the flock consists of, say, 1,000 or more sheep. Lambs' wool should also be baled in two lots—first or A lambs in small clips, or A in larger clips, should be the longest and brightest wool, and the second class all the duller and shorter wool. A bale must weigh over 250lbs., but should not exceed 360lbs. A good average weight is about 320lbs. to 330lbs. All bales should be numbered and branded across the top and on the front side. The larger the number of fibres to the area of a sheep's body, the greater the density of the wool."

October 13th.—Present: 19 members.

**FALLOW CULTIVATION.**—Mr. J. Schilling read the following paper:—Cultivation of the fallow is one of the most important jobs on the farm. The land should be worked well the first time of cultivating, this being done before summer while the soil is moist, thus minimising take-all. If fallow is not worked well the first time, a good crop can very seldom be expected; it is not necessary to work the ground deeply after the first cultivation. The fallow should be kept clean and free from weeds and fairly loose during the summer months so that air can penetrate the soil. It always pays to work the fallow several times during the year; since we adopted this method we have always had good

results. We tried a few acres the first year and could see the difference at harvest time in the crop, it being thicker, higher, with longer heads and better grain than that which had only been cultivated once or twice. Fallow should be cultivated again at least a month before seeding to allow the soil to set again. It is not a good plan to start seeding immediately after cultivating, because the ground generally is worked down too fine. At the present time, farmers mostly use combines for seeding and it makes a perfect job of cultivating when the fallow is loose, but the most suitable implements are the scarifier or spring-time cultivator when the ground is hard or cultivating the first time after ploughing. When there are troublesome weeds to contend with, a scarifier is not good enough; the weeds are dragged over the paddocks and again take root. The skim plough has proved a good implement to kill sorrel and other weeds, but is no good for working fallow the first time. Another suitable implement for cultivating is the disc cultivator, it being just as good as a scarifier or spring-time cultivator, and it does not leave a wheel track on the worked ground. The disc cultivator does not leave the ground too rough nor too fine; it kills weeds and will go through any thick rubbish, but it does not do good work in sticky ground when it is wet. During the discussion on the paper, Mr. Johnston stated that aeration of the ground was a most important factor in fallow cultivation. Take-all was encouraged by not having a solid seed bed. He favored the rigid or stump-jump to spring-time or disc implements. One should not work red ground too finely on account of its running together. Fallow should be cultivated a couple of times about October, then in the summer if weeds were present, and again after the first seeding rains. To eradicate sorrel, apply 6cwt. to 8cwt. of lime to the acre immediately after the first ploughing; spread it on top of the ground, but do not work it in. Spray sour sobs with sodium chlorate if in small patches only.

The annual meeting was held on January 12th, there being present 12 members. The Hon. Secretary (Mr. L. Davis) presented the annual report, and officers were elected for the ensuing year.

#### TWO WELLS (Average annual rainfall, 15.88in.).

The annual meeting of the Branch was held on September 4th, and was attended by 20 members and about 120 visitors. Mr. C. G. Lewis gave an address illustrated with lantern slides, "The Coral Islands and Marine Gardens of the Great Barrier Reef." Elocutionary and vocal items were rendered. (Secretary, Mr. M. Pratt.)

#### WASLEYS.

September 11th, 1930.—Present: 45 members.

**ANIMAL, BIRD, AND INSECT PESTS.**—In the course of an address on this subject, Mr. V. Day said that animals such as foxes and rabbits had been imported for sporting purposes, but were now a pest to farmers. He did not favor poisoning either of these pests, because there was a danger of the dead carcasses being picked up and chewed by cattle, which would probably result in the loss of the animals. He considered hunting the fox the best means of destruction, and ferrets to hunt the rabbits from their warrens. Skins and carcasses were valuable, and repaid trapping or hunting. Rats, he considered, were the worst of animal plagues, and to destroy them either gas, tar, or hot water poured into their haunts was the cheapest method of destruction. Speaking of bird pests, he considered that many of the protected birds were a worse pest than the unprotected. Quails should be saved from slaughter, because they destroyed weed seeds. Hawks, eagles, crows, &c., cleaned up much of the waste matter from ewes after lambing and destroyed the maggot of the blowfly. Those birds were blamed very often for killing lambs, but he assured members that they would not touch a lamb while life existed. Magpies he considered a nuisance to the poultry yard. They killed chickens, and if they commenced taking eggs, were worse than crows. Sparrows could be destroyed with poison wheat prior to seeding. Speaking of insect pests, he said sheep affected with lice should be dipped. Blowflies should be kept down by burying or burning all dead animals, the carcasses of which were a breeding place for flies. Sheep should be inspected occasionally and crutched if required, and if fly blown, turpentine 1 part, mixed with 2 parts of medium body oil, applied. Merinos were particularly needful of attention owing to the density of the wool. The bot fly was a pest and troublesome to horse teams. A little oil of turpentine should be applied to places where flies struck. For the following insect pests, Mr. Day suggested:—Horse louse, turpentine and oil to affected parts; fowl tick, dip fowls or put oil on perches; fleas, applications of turps and oil; weevil, reap grain when properly ripe. Common fly should be caught by flypaper, &c. In the discussion, Mr. E. Day considered the fox a bad pest, but it was often blamed for damage done by stray dogs, and that a more strict enforcement of the Registration of Dogs Act would assist in combating these

nuisances. Foxes did destroy plovers, curlews, and quail, which were friends of the farmer. The latter destroyed night insects and consumed weed seeds. Boys should be encouraged to gather sparrow eggs. Magpies were great insect catchers, and he did not consider them a pest. For blowfly maggots he used petrol; although severe at first, it was very effective, and the severity of it soon passed off. For poultry lice, before setting the birds, lime should be sprinkled in the nest, and the bird with insect powder. Mr. E. Fischer said that the best method to destroy foxes was to place two eggs out side by side, strychnine treated; but care should be taken not to handle them with the hand. By this method the chance of the fox getting away with both eggs was negligible. (Secretary, Mr. C. Currie.)

---

## YORKE PENINSULA DISTRICT.

(TO BUTE.)

BRENTWOOD (Average annual rainfall, 15.52in.).

A meeting on September 4th was attended by 21 members and visitors. Mr. J. Boundy delivered an address, "Power Farming v. Horses." A discussion followed, in which the majority of members were of the opinion that horses must again come into favor.

A further meeting was held on September 30th, with an attendance of 24 members and visitors. The subject was an address by Mr. R. Hill (District Agricultural Instructor), "Conservation of Fodders."

Twenty members and visitors were present at a meeting on October 29th. Mr. H. B. Barlow (Chief Dairy Instructor) addressed the meeting on dairying matters and replied to numerous questions. (Secretary, Mr. G. Tucker.)

---

## WESTERN DISTRICT.

ELBOW HILL (Average annual rainfall, 11in. to 12in.).

September 3rd.—Present: 13 members.

Mr. J. A. Elleway read a paper, "Advantages of Power Farming." He had been power farming for five years. He said horses had to be fed 365 days a year whether they were working or not. It was not always convenient for the farmer to have a good supply of surplus hay on hand, and he was very often unexpectedly faced with a drought. The tractor eliminated much of the drudgery attached to farming; the cleaning out of stables, grooming, and harnessing of horses was dispensed with. During rush periods there was no changing of teams and no need to wait because it was too hot for the horses to work. The farmer had to keep the best of his grass paddocks for his horses. If horses were not used, the land could be put to more productive uses, such as for cows or for grazing sheep. His tractor expenses over a period of five years had not amounted to more than £25 or £30, including the cost of two sets of lugs. During the past five years, if he had been working horses, he would have been carting water for months. However, because he had a tractor, he had been able to put all his spare time into improving the farm by such work as fencing, stone picking, &c. If a tractor were overhauled about twice a year a breakdown would seldom occur. He had never experienced one since having a tractor. The life of the machine depended mainly on the operator and the size of the implements it pulled. In some years horses might work more cheaply or as cheaply as a tractor, but he thought that if the average cost were taken over a period of years, the tractor would work out by far the cheaper, on large farms as well as on small ones. In fact, it would be cheaper on the small farm, because the farmer had not enough land to carry a horse team as well as cows and a few sheep. A paper, "Horses v. Tractors," by Mr. R. F. Wake, was also read. A good discussion followed.

At a further meeting on January 7th, which was attended by 11 members and visitors, Mr. Wake delivered an address on his visit to the Waite Agricultural Research Institute. (Secretary, Mr. W. J. Cooper.)

---

## KAPINNIE.

September 19th.—Present: 19 members.

FENCING.—In the course of a paper on this subject, Mr. D. Green said good fences added to the attractiveness of a holding, and every farmer should have strong fences surrounding his property. A good fence could be made of posts 3in. or 4in. across the top. In that district it was hard to get good timber for posts. Native pine was best, then titree. They were both light posts for carting and easy to bore. The best height for a fence was 8ft. 8in., and it was advisable to get rid of any animals which would not stay inside a fence of that height. In the discussion which followed Mr. Wagner said 3ft. 4in. was high enough for a fence. (Secretary, Mr. E. Wannan.)

### KELLY (Average annual rainfall, 11.92in.).

Mr. C. Freeth presided over an attendance of 15 members and six visitors at the meeting on September 6th, which was held at the residence of Mr. J. Guthleben. Crop competitions and other matters of local interest were discussed. (Secretary, Mr. M. Martin, Kimba.)

### LIPSON.

A meeting on September 27th was attended by eight members and three visitors. Eight members attended a further meeting on November 8th. Matters of local interest were discussed. (Secretary, Mr. M. Barraud.)

### PALABIE.

The monthly meeting was held on September 4th with an attendance of 11 members. A paper, "Gardening Notes," was read by Mr. H. North, who also replied to several questions on the subject. A paper read by Mr. C. Rashleigh, "Side Lines on the Farm," was fully discussed. Members also took part in a discussion on the value of cows, fowls, and pigs.

Eleven members attended a meeting on October 3rd. Delegates gave a report on the proceedings of the Annual Congress. Mr. E. Rashleigh read a paper, "Horses versus Tractors." He favored horses because they were more economical where they had to be worked for 10 to 12 months of the year. A team of 10 horses was cheaper to buy than a tractor, and the working expenses per acre were practically the same, but with a tractor the feed grown on the farm could be taken as a profit. Sixteen tons of hay would be sufficient fodder on which the team would do the bulk of the work of seeding and fallowing, and the actual cost of the 16 tons worked out at £44 15s.—approximately £3 per ton. The average team would consume one ton per week, which gave 16 weeks working feed. In most years one could get, say, 12 weeks stubble feed, leaving 24 weeks to feed off 200 acres of pasture. That referred to a farm of approximately 1,000 acres, allowing for cropping 500 acres, fallowing 300 acres, and leaving 200 acres for pasture. The writer stated that after five years service the depreciation on a tractor would be approximately 50 per cent. With a 10-horse team in five years one should have a new team ready to start work, whereas with a tractor the farmer would be very fortunate if at the end of five years he did not have to spend more on the tractor than it cost to raise a new team of horses. Another point to consider was that when seeding the drill could be worked close to the fence, and at harvest time the tracks around the fence could be cut to feed the stock, whereas with a tractor it generally ran over the crop which was left on the ground. A lively debate followed Mr. Rashleigh's paper. Several members favored the tractor for quick working, but considered that working cost per acre was lower where horses were used.

A further meeting, in the form of a Question Box, was held on October 31st, with an attendance of 12 members and three visitors.

A meeting was held on December 5th. Ten members and two visitors were present. A paper was read by Mr. H. Luestner. (Secretary, Mr. E. Rashleigh, Wudinna.)

### MALTEE.

The monthly meeting on September 11th was attended by 14 members and visitors. Mr. A. Edson gave an address on sheep shearing, and a good discussion followed.

"THE ECONOMIC POSITION OF THE PRIMARY PRODUCER" was the subject of a paper by Mr. J. B. Talbot at a meeting on October 2nd; 20 members and visitors were present. Referring to high land values, Mr. Talbot said that, although land in the better rainfall areas had been affected, in the class of country similar to their district, nothing could be laid to that charge, because land values were but very little higher than they were 20 years ago. There was no doubt that the low prices for products had affected the position to a large extent, but only in relation to the high costs of production, because many would remember when both wool and wheat were as low in price, or even lower, than the present, and yet farmers paid their way and had a surplus. The writer was not in favor of the pool system of marketing primary products. He thought that holding wool for high prices had led to the introduction of artificial wool, and, in the case of wheat, had caused the peoples of the world to turn to substitutes. The position could largely be improved by lower costs of production. Lower rail freights and the abolition of wharf and jetty tolls on outward bound products would help a great deal. Increased yields of wool by better fleeces and of wheat by larger yields per acre were two factors which would help to improve the position. However, they were both largely dependent on climatic conditions. There were many lines in which a saving could be made by co-operative buying and selling. By co-operative selling he did not mean the pooling system, but combining and selling in larger parcels, which in most cases brought a higher price than small lots.

A further meeting on October 30th was attended by 15 members and four visitors. The delegates delivered a report of the Annual Congress.

The monthly meeting on November 27th was attended by 15 members and three visitors. Mr. J. Kerin read a paper written by Mr. W. J. Spafford for the Annual Congress. A good discussion followed.

Fourteen members and two visitors were present at the meeting on January 8th. Mr. J. W. Bassham read a paper written by Mr. Fisher, and a discussion took place. (Secretary, Mr. E. Schwarz.)

**MANGALO** (Average annual rainfall, 14in. to 15in.).

At a meeting held on September 1st Mr. O. Hannemann read an article dealing with the Federal Wheat Marketing Scheme. The question of wheat marketing was discussed by members. (Secretary, Mr. C. Hannemann.)

**MILTALIE** (Average annual rainfall, 13.59in.).

September 6th.—Present: 19 members and four visitors.

**VALUE OF SIDE LINES ON A FARM.**—In a paper on this subject, Mr. D. Bagnell said in latter years with either wheat or wool realising fair to good values the man on the land could generally make a fair to good living, but to-day the burden of excessive rates and taxes, coupled with the high cost of production, such as farm implements and machinery, cornsacks, super, wages, living, &c., compared with the very low prices of wheat and wool, put the landowner in a bad position. There was need for economy, and to do that he thought that side lines would be a step in the right direction. For instance, the farmer who had a large family should be able to put on the market in a presentable way poultry, butter, pork, eggs, &c., in large quantities. Where there was a large family on the holding cows, pigs, fowls, and gardening could bring in quite a big revenue, providing there was a market and transport difficulties were not too great. Where cows were a side line, too many inferior breeds were kept. Inferior cows meant poorer returns and cost just as much for maintenance, therefore it paid to keep a good milking strain. When selling them or their progeny, one could always demand a good price. He considered that in their district the cream can was an

effective and profitable way of marketing the products. Where there were a number of cows kept, pigs could be raised profitably. They should be sold from six weeks to six months old, it was cheaper to breed them than to keep fully grown pigs. Poultry was a side line which appealed to most. It was easy to run, and that was where a big mistake was made; too little attention was paid to the housing, feeding, and breeding of the birds, and very often less in the gathering and marketing of the eggs. He did not see why one should pay half a guinea to a guinea for a setting of eggs, or £5 per hundred for day-old chicks, when one could do one's own breeding and be a seller instead of a buyer. The housing and feeding of the poultry should not be neglected, and the chicks should be raised to lay in winter months when eggs were dear. Gardening in their district had not proved itself a payable proposition, chiefly due to the lack of irrigation, but an effort should be made to grow enough vegetables for the household. There were other so-called side lines, such as carriers, handy men who went out on odd jobs, contracts, &c., but usually such lines were not altogether payable, because the farmer had to stick to his own farm to get the best returns and should not take on any side lines which would interfere with seeding or harvesting operations, or retard the progress of his farm. A keen discussion followed.

At a meeting held on October 4th there was an attendance of 24 members and four visitors. A paper, "The Value of Barley as a Fodder," was read by Mr. S. McCauley. He said that wheat growing at the present time was not showing the farmer a profit, but, on the other hand, in many cases showed a distinct loss, hence they had to look to other means to help to make up their losses, meet liabilities, interest, wages, &c. If they were to find a solution to their problems he thought it might be found in the production of barley as a fodder. It was not known perhaps as well as it might be that barley as a corn feed was equal to any corn produced in Australia to-day. A lot of people held the idea that it was too heating as a corn feed; that was not so. Barley could be fed even to horses at the rate of 1bush. of pure grain per day without any harm resulting. Half a pound per day would keep a sheep in good, strong condition, and would give a ewe rearing a lamb a good supply of milk. It was also a good milk producer for cows, a good fattener for pigs, producing nice, even bacon. and it was equal to most other grains for feeding fowls. The two varieties he advocated were the four-row Cape barley and the two-row Pryor's malting. He had made a special study of the latter, and had grown it under nearly all conditions. He had grown it as a grain for malting, but their district would not produce a malting quality except under very favorable conditions. On account of the situation and the dry winds during the growing and ripening period, the grain became callous or flinty, and ripened with a brittle or hard shell, which was not suitable for the maltster, though it did not affect the feeding quality to any great extent. The advantage with two-row barley—so far as production was concerned—was its short growing period. It could be sown after the wheat and reaped before the wheat was ripe. He had sown it at the latter end of August and reaped 35bush. to the acre in November. The best crops had been produced from grass land, summer fallowed as late as January. Barley seemed to do remarkably well on that type of cultivation, but would also produce a fair crop from stubble land. Some people were inclined to think that barley impoverished the land and encouraged take-all. The writer had grown it for five years in succession with an average of nine bags to the acre over that period, and followed the last crop by fallow and reaped 30bush. of wheat from the same land the following year. He contended that in their district, where there was a good deal of grazing land mixed with agricultural land, by growing a cheaply produced grain which would grow with a light rainfall, the sheep-carrying capacity could be increased by 50 to 60 per cent.; in fact, there was no reason why by proper and systematic working it could not be increased by 100 per cent. Wool, even at 6d. per pound, was a better paying proposition under present conditions than wheat produced at 3s. per bushel. Storing the barley would perhaps be the biggest problem, because barley seemed to be much harder than wheat to keep free from weevil. The trouble could be overcome by using silos, or a concrete shed, or even by tipping out loose in a shed with a good floor. A certain amount of barley could be cut for hay and fed as chaff, and one would have the double advantage of the chaff as well as the corn. If barley was left fairly late, the corn ripened after binding and made very good chaff; in fact many farmers on Yorke Peninsula were cutting a lot of barley for hay and mixing layers of it through their stacks of oat or wheaten hay on account of the value of the corn, it saving them from corn feeding with the chaff. In the course of the enthusiastic discussion which followed Mr. F. Coles said that the growing of a green fodder, such as barley for sheep feed, and also to produce grain for hand feeding over the lean period, seemed essential in their district. It would stabilize the number of sheep that could be kept on a farm. For feeding off purposes, Mr. W. Smith favored a mixture of half oats and half barley. Mr. J. Jacobs did not think barley would

thrive in the district, and stated that it was a difficult grain to handle. Mr. F. Jacobs advocated barley because it produced a good growth of early feed ahead of most other cereals. It was a fallacy that by growing barley the land became infested with it and interfered with wheat growing, because where stock could get to it barley was rarely known to get ahead. Mr. S. Bagnell found barley the best feed of any cereal. It got away early and stock thrived on the stubble. Mr. Story considered that when fed to sheep it did not affect the quality of the wool. He had known Cape barley to yield up to 40 bush. in their district during wet seasons, but for feeding purposes it was not so good as malting barley.

The monthly meeting held on November 1st was attended by 12 members. A paper, "The Improvement of Our Flocks," was read by Mr. F. Jacobs. He considered that although the price for wool was low and sheep cheap, they were one of the most important lines to look to in a time like the present. Because they were cheap they should not be neglected. There was never a more opportune time to improve flocks than the present owing to the lower prices ruling for high class sheep. To improve the flocks the first necessity was to have a good boundary fence, to see that the sheep had plenty of feed and good, clean water, with free access to salt. To use the best rams one could procure was a very important factor. Money spent on good rams was essential, because without them little or no improvement could be expected. A bad ram would get more mongrels than a good ram would get good sheep. Another way in which flocks could be improved was by clearing the country as much as possible. However, one should not neglect to leave sufficient shade, because without shade the fleece tip became bleached and faded like dead wool. It then opened and let in the dirt and destroyed the life of the whole fleece. By using more super on the land the writer had proved that the fleece would be heavier and the wool stronger. Feed conditions altered the count of the fleece more than most people realized. For instance, a sheep running on good natural grass that had not been cultivated or manured, which carried 64 count wool, when put on to heavily manured land would immediately start to grow a 60 count wool. He had proved that on his own land. Therefore, in selecting rams one should take into consideration the condition of the feed on which the rams had grazed and make allowance accordingly. If paying a big price for a ram he advised buying only on condition that the ram was satisfactory after being shorn, because it was surprising what defects could be hidden with the wool by expert shearing, such as devil's grip, camel humps, goose rump, lop-sided folds, breech wrinkles, hairy breech, and bad tails. If one had good sheep he advised considering well before sending one's best ewe lambs—which were usually the fattest—to the freezers, and then have to keep the culls. Even when using long wool breeds with the idea of rearing lambs for the freezers, they were up against the same trouble of not knowing what to do with the rejects. He advised keeping the large-framed Merino and using plenty of barley and oats and super to provide green fodder and grain. He was sure they could then in ordinary seasons supply quite a lot of good lambs for the freezers. Sheep could run on fodder crops during winter and spring, and later on the stubbles, and be fed with corn and chaff. Even cocky chaff would be quite all right during any time of shortage of sufficient feed in the paddocks to keep the clip growing. He preferred a feeder of any description to throwing feed on to the ground. If intending to feed lambing ewes, it was not advisable to wait until they started lambing, or the results would be very disappointing. During the discussion which followed, Mr. W. Smith said that the present wool prices would entice pastoralists to produce a better quality wool if they expected their business to pay. He favored a fine quality wool—60's to 64's—because the demand was always keen for that class. Mr. G. Smith thought they should strive to increase both the weight of wool per sheep and the sheep carrying capacity of the land. Grazing the flocks on sown pastures over certain periods of the year and spelling other portions of the holding would greatly increase the carrying capacity. (Secretary, Mr. G. Smith, Cowell.)

#### MINNIPA (Average annual rainfall, 14.68in.).

The monthly meeting of the Branch was held on September 11th, and was attended by 10 members. Mr. J. Martin gave a demonstration on poultry keeping. (Secretary, Mr. F. Williams.)

#### MOUNT HOPE.

The monthly meeting was held on September 8th, with an attendance of eight members. Mr. W. Vigar read a paper, "Accessories on the Farm." He said the chaffcutter and engine were important accessories, because although it was possible to get good results from feeding long hay or fodder, chaffing it saved considerable time in feeding, and there was not nearly so much waste as with long fodders. The engine could also be used for pumping water, thereby assuring a supply of water whether

the wind blew or not. Another use for the engine was in sawing a wood supply. A most useful accessory was a well-equipped blacksmith shop. Much time and money would be saved by the farmer who did the farm's general repairing himself. Most farmers could repair minor breakages as well as a professional, and while such work as retyring a wheel or welding a broken sprocket or cog were jobs for experts, such things as making bolts, eyebolts, C or S hooks, and welding flat or round iron were quite within the capability of the novice. Motor cars and motor cycles were among the most popular accessories to farming to-day. Personally he considered that a motor cycle should be found on every farm, since it combined the qualities of a saddle hack with the speed of a motor car. Moreover, it had the advantage of always being at home when wanted. Perhaps the farmer's most useful accessory was the dairy. Sheep could also come under the same heading from a strictly wheat growing standpoint, for they could turn stubble into revenue. Poultry also assisted the management of the home, but they should not be allowed the full run of the farm. The vegetable garden was also of value. Stable manure was the best manure for the garden, and with plenty of water enough vegetables could be grown by the average farmer to provide for the household requirements.

A meeting was held on October 7th, with five members present. Mr. R. Myers read a paper, "What is the Most Profitable Side Line?" He stated that in these times of high costs and low prices for primary products it was essential for farmers to turn attention to side lines in the hope of augmenting their income. In view of the fact that Eyre Peninsula had its freezing works already established, the time was opportune for raising fat lambs. Farmers, most of whom were still resident on the Peninsula, had about £38,000 invested in those works, for which they were getting no interest, and if the works could be put into profitable operation it would be a great relief to Eyre Peninsula, not only to the farming community, but also to the pastoralist, who would have a ready sale for surplus breeding ewes. To achieve the desired effect, some organising work was necessary, firstly to educate the farmer along the right lines for working, and secondly, to provide transport facilities for conveying the lambs from the farm to the works. He felt confident that now that the Peninsula had an adequate water supply, there was nothing to hinder the development of this most important industry. In the past, when wheat and wool prices were at a high level, it was impossible to interest the farmer, but now that the position had changed, farmers and pastoralists should not hesitate to give the business a trial. He suggested that the Agricultural Bureau should take the matter up and that each Branch should do all in its power—with the aid of the departmental officers—to ascertain what each district could do in the matter. The departmental officers who toured the country could do all that was necessary in the way of educational work without incurring any additional expense. (Secretary, Mr. J. Vigar.)

#### MUDAMUCKLA.

Meeting held September 11th. Present: 12 members. The agenda for the 1930 Annual Congress was discussed. (Secretary, Mr. T. Zippel.)

#### PINBONG.

The meeting of September 6th was held at the residence of Mr. H. Scholz. An address, "Fallow and its Working," was delivered by Mr. W. H. Brownrigg (District Agricultural Instructor). (Secretary, Mr. C. Scholz, Yaninee.)

#### PINKAWILLINIE.

The meeting of September 6th was presided over by Mr. F. Freeth. Matters relating to crop competitions, Kimba Conference, and the Annual Congress were discussed. Eleven members and several visitors attended. (Secretary, Mr. S. Johnson.)

#### ROBERTS AND VERRAN.

September 3rd, 1930.—Present: Eight members.
